The Dissertation Committee for Damayanti Chakraborty

certifies that this is the approved version of the following dissertation:

**NATURAL KILLER CELLS, HYPOXIA, AND EPIGENETIC REGULATION OF
HEMOCHORIAL PLACENTATION**

Chair: Michael J. Soares, Ph.D.

Date approved: 04/01/2013

ABSTRACT

During the establishment of pregnancy, uterine stromal cells differentiate into decidual cells and recruit natural killer (NK) cells. These NK cells are characterized by low cytotoxicity and distinct cytokine production. In rodent as well as in human pregnancy, the uterine NK cells peak in number around mid-gestation after which they decline. NK cells associate with uterine spiral arteries and are implicated in pregnancy associated vascular remodeling processes and potentially in modulating trophoblast invasion. Failure of trophoblast invasion and vascular remodeling has been shown to be associated with pathological conditions like preeclampsia syndrome, hypertension in mother and/or fetal growth restriction.

We hypothesize that NK cells fundamentally contribute to the organization of the placentation site. In order to study the *in vivo* role of NK cells during pregnancy, gestation stage-specific NK cell depletion was performed in rats using anti asialo GM1 antibodies. Robust endovascular trophoblast invasion and vascular remodeling were observed in NK cell depleted animals. This depletion affected mesometrial vasculature, lowered relative oxygen concentrations at the placentation site and altered trophoblast lineage commitment at gestation d9.5. There was also a significant change in the organization of the chorioallantoic placenta on d13.5. Delivery of oxygen appears to be a key signal influencing both trophoblast cell differentiation and organization of the placentation site.

Hypoxia promotes development of the invasive trophoblast lineage. We next evaluated the impact of hypoxia on the trophoblast stem (TS) cell transcriptome. DNA microarray analysis was performed on rat TS cells exposed to atmospheric and low oxygen (0.5%). Upregulation of genes characteristic of an invasive phenotype and a marked downregulation of stem state-associated genes were observed. Matrix metalloproteinase 12 (*Mmp12*) and lysine demethylase

3A (*Kdm3a*) were markedly upregulated in response to low oxygen, while E-cadherin (*Cdh1*) expression was dramatically decreased. These responses were dependent upon hypoxia inducible factor (HIF) signaling. Several of the HIF targets were identified to be *Kdm3a* targets. KDM3A acts on dimethyl and monomethyl histone H3K9 substrates, which prompted an examination of global histone H3K9 methylation status of trophoblast cells developing *in vitro* and *in vivo*. Hypoxia significantly impacted histone H3K9 methylation. Knockdown of KDM3A in TS cells inhibited hypoxia-induced *Mmp12* gene expression and disrupted histone H3K9 methylation status at the *Mmp12* locus.

Ectopic expression of KDM3A stimulated MMP12 expression. KDM3A knockdown also significantly decreased hypoxia-activated TS cell invasion through Matrigel chambers. Finally, blastocysts transduced with *Kdm3a* shRNA expressing lentiviral particles showed reduced outgrowth when exposed to low oxygen tensions. In summary, NK cells impact oxygen delivery and uteroplacental adaptive responses, influencing critical lineage decisions affecting trophoblast differentiation and the ultimate structure and function of the chorioallantoic placenta. Hypoxia/HIF-directed epigenetic remodeling via KDM3A contributes to the control of TS cell adaptations during placentation modulating trophoblast lineage commitment and invasion.

ACKNOWLEDGEMENTS

I would like to thank my family for the unrestrained support, guidance, and encouragement that I have received from them over all these years. My father Mr. Janak Chakraborty has always instilled in me a love for science, and encouraged me to pursue my dreams of becoming a scientist wholeheartedly. My mother, Ms. Swati Chakraborty has been instrumental in imparting strong values, both moral and ethical, and an unflinching sense of commitment and integrity. I shall be forever grateful to the both of them. Special thanks to my brother Mr. Arnab Chakraborty (Tito), for helping me realize the spirit of sharing and teamwork, which was extremely valuable during my tenure as a graduate student in the laboratory. I would like to thank my best friend and collaborator, Dr. Aritra Bhattacharjee, for some very stimulating scientific discussions and brainstorming sessions, which contributed significantly towards designing experiments and interpreting experimental outcomes.

I would like to thank my mentor Dr. Michael J. Soares, for supporting me, and nurturing and shaping my scientific endeavors. Without his support, this work would scarcely have been possible. His scientific spirit and enthusiasm has been quite infectious, and I hope to carry on my future research activities based on his foundation of strong scientific ethic and commitment. I would also like to thank Dr. Mohammad Rumi for his help and advice with Molecular Biology and his superior guidance in helping me delve into uncharted scientific territories fearlessly.

My heartfelt thanks to Dr. Toshihiro Konno, for his advice on histological techniques, and on developing a camaraderie amongst fellow lab members. I would like to thank my committee members, for their continuous help and advice in guiding my research project. I would also like to thank Ms. Stacy McClure, Ms. Jackie Jorland and Ms. Lesley Shriver for their

support and administrative help. Special thanks to Ms. Jorland for helping me acquire the tools and reagents for my experiments, without which all of the research work would not have been possible. I would like to acknowledge all members of the Soares Laboratory (past and present), who helped me with their scientific and non-scientific advice, making me a better scientist in the process.

I would like to thank Dr. Sumedha Gunewardena and Clark Bloomer in the Bioinformatics core (University of Kansas Medical Center) for helping me with generation and analysis of microarray data. I would like to thank my collaborators Dr. Kunio Shiota from University of Tokyo, Japan and Dr. Christopher Mack from University of North Carolina, Chapel Hill for kindly providing me with reagents that were valuable for my research. Last but not the least, I would like to acknowledge American Heart Association and Biomedical Research Training Grant Program (University of Kansas Medical Center) for providing me with fellowship which has partially supported my research activities.

CHAPTER1:

GENERAL INTRODUCTION

The maternal –fetal interface

The maternal fetal interface is a dynamic site undergoing pregnancy associated adaptations (Enders and Welsh, 1993). The most important adaptation is extensive vascular remodeling of the maternal spiral arteries to facilitate nutrient flow and gas exchange in the growing fetus (Adamson et al., 2002; Kaufmann et al., 2003; Red-Horse et al., 2004; Vercruysse et al., 2006). An elaborate arterial-venous network is established that supplies the placenta. As gestation progresses, small uterine spiral arteries supplying the placenta are modified creating flaccid, low resistance blood vessels (Adamson et al., 2002; Christofferson, 1993; Pijnenborg et al., 2006; Takemori et al., 1984; Takemori et al., 1985). Uterine natural killer (NK) cells and invasive trophoblast cells have been identified as two key players mediating these pregnancy associated vascular changes (Croy et al., 2000; Moffett and Loke, 2006a, b; Vercruysse et al., 2006).

The rat as a model for studying biology at the maternal-fetal interface

Animal model systems are essential tools for studying and manipulating molecular mechanisms that govern cellular development. The maternal-fetal interface is no exception. The rat and the human both possess hemochorial placentation (**Fig. 1.1**). The idea of studying any animal model system is that if the process being studied is fundamental, most likely it will demonstrate conservation across species. Although, there are some differences in the organization of the rodent versus the primate maternal-fetal interface, overriding similarities in the lineages of cells comprising the maternal-fetal interface and their functions exist. Among these are the processes and changes taking place during the last week of gestation in the rat. During this latter phase, trophoblast cells move out of the chorioallantoic placenta and invade into the uterine endometrium, where they establish intimate relationships with the uterine

vasculature (Adamson et al., 2002; Ain et al., 2003a; Caluwaerts et al., 2005; Coan et al., 2006; Vercruysse et al., 2006). These invasive events in the rat are remarkably similar to invasive events taking place during the latter stages of the first trimester and throughout the second trimester of pregnancy in the human (Kaufmann et al., 2003; Red-Horse et al., 2004; Vercruysse et al., 2006).

Placentation in the Rat

The placenta is an important organ during gestation, which functions as a conduit between the mother and the developing fetus. It is specialized to facilitate and coordinate maternal adaptations to pregnancy and fetal development. The placenta is primarily comprised of trophoblast cells, which perform a number of specialized functions. Implantation brings about differentiation of mural trophoctoderm (trophoctoderm not in contact with the inner cell mass) to post-mitotic trophoblast giant cells (TGC). These cells move anti mesometrially and surround the future parietal yolk sac. The polar trophoctoderm (trophoctoderm in direct contact with the inner cell mass) proliferates and expands to form the extraembryonic ectoderm and the ectoplacental cone (Gardner et al., 1973). Pluripotent trophoblast stem (TS) cells are found in the extraembryonic ectoderm and later on in the chorionic ectoderm (Tanaka et al., 1998; Uy et al., 2002). They supply the ectoplacental cone with precursors for the spongiotrophoblast lineage and the secondary TGC. During mid-gestation, the rodent placenta has a layer of TGC and the developing chorioallantoic placenta (**Fig. 1.2 A&B**). The developing chorioallantoic placenta further acquires distinct structural and functional specifications as pregnancy progresses. The mature placenta is comprised of two morphologically and functionally distinct layers : the junctional zone and the labyrinth zone. Progenitor cells, spongiotrophoblasts, glycogen cells, and an outer layer of TGCs comprise the junctional zone.

Fig. 1.1 Schematic representation of the general organization of the hemochorial placenta.

In hemochorial placentation trophoblast cells invade into the uterus both interstitially and endovascularly. Uterine NK cells and invasive trophoblast cells are two key players at the maternal fetal interface.

The invasive trophoblast lineage is known to arise from progenitors within the junctional zone region (Wiemers et al., 2003). During the last week of gestation, these cells move out of the placenta and invade into the maternal uterine mesometrial compartment. The innermost layer of the placenta is the labyrinth zone which consists of trophoblast cells and fetal vasculature derived from the allantois. Progenitor trophoblast cells within the labyrinth zone fuse to form syncytia, which provide barriers between maternal and fetal compartments. The labyrinth zone consists of an elaborate branched structure, providing a large surface area for nutrient, waste and gas exchange with the fetus.

Blastocyst derived rat trophoblast stem (TS) cell

Rat trophoblast stem cells (**Fig. 1.3**) represent an excellent model system to study effects of low oxygen signaling *in vitro*. These cells were derived from d4.5 rat blastocysts cultured on rat embryonic fibroblasts (REFs) in RPMI-1640 culture medium supplemented with 20% FBS, FGF4, and heparin. Once cell lines were established, the REF feeder layers could be replaced with REF conditioned medium (Asanoma et al., 2012).

In the proliferative state, cells express established markers of TS cells, including Cdx2 and Eomes. Cells ceased proliferation and differentiated when FGF4, heparin, and REF conditioned medium were removed. Differentiation was characterized by the decline of Cdx2 and Eomes expression, the appearance of large polyploid cells (trophoblast giant cells), and the expression of trophoblast differentiation-associated genes, including Prl3b1 (PL-II, trophoblast giant cells), Tpbpa (spongiotrophoblast), Cx31 (glycogen cells), Prl5a1 (PLP-L, invasive trophoblast), and Gcm1 (syncytial trophoblast). The capacity of rat TS cells to express different lineage associated genes which are also observed *in vivo* during trophoblast differentiation and

Fig 1.2A Multi-lineage trophoblast cell differentiation. In mouse and rat, trophoblast cells differentiate into several lineages. Junctional zone precursor cells can give rise to trophoblast giant cells, spongiotrophoblast and glycogen cells. Labyrinth zone precursor cells differentiate into syncytial trophoblast. **Fig 1.2 B Organization of a mature rat placenta.** Beginning midgestation the placenta is comprised of two distinct zones, the junctional zone harboring the precursors of invasive trophoblast lineage and the labyrinth zone composed of syncytiotrophoblast cells.

A

B

placenta formation, makes them an excellent tractable model to study hypoxia dependent adaptations *in vitro*.

NK cells and the uterine vasculature

Pregnancy results in a highly regulated allocation of immune cells to the uterus (Bulmer and Lash, 2005; Croy et al., 2002; Croy et al., 2003; Head, 1996; Hunt et al., 2000; Kruse et al., 1999; Kruse et al., 2002; Moffett-King, 2002). Following embryo implantation most leukocytes are excluded from the maternal uterus except for NK cells which constitute almost 70% of the leukocyte population in the uterus during pregnancy.

NK cells are conspicuous cellular constituents of uteroplacental compartments from rodents and primates (Bulmer and Lash, 2005; Croy et al., 1996; Dosiou and Giudice, 2005; Hanna and Mandelboim, 2007; Head, 1996; Liu and Young, 2001; Moffett-King, 2002; Moffett and Loke, 2006a; Parham, 2004; Sargent et al., 2006). Implantation associated decidualization in the rat and mouse, results in expansion of NK cell numbers in the maternal uterine mesometrial decidua (Ain et al., 2003a; Croy et al., 1996; Head, 1996). The uterine mesometrial compartment receives the mesenteric blood flow and it is the region overlying the developing chorioallantoic placenta. By midgestation, NK cells migrate away from the decidual region and associate with the mesometrial vasculature (**Fig. 1.4**). The mesometrial vasculature is organized in a triangular shaped area between the mesometrial decidua and the mesometrial surface of the uterus and has been referred to as the metrial gland, and several other terms (Ain and Soares, 2004; Peel, 1989). These mesometrial blood vessels are responsible for the nutrient flow to the placenta and fetus.

Fig. 1.3. Overview of rat trophoblast stem cell model. The rat trophoblast stem (TS) cells can be maintained in a stem cell state or induced to differentiate by removal of FGF4 and rat embryonic fibroblast (REF) conditioned media. Differentiated cells have distinct cellular morphology comprising of various lineages.

Stem

Removal of FGF4, HEPARIN
and REF conditioned media

Differentiated

NK cells are implicated in uterine vascular development (Croy et al., 2002). Lack of NK cells is associated with profound alterations in the uterine mesometrial vasculature. Several mouse models of NK cell deficiency (transgenic mice expressing a human CD3 ϵ gene, Tg ϵ 26, recombinase activating gene-2 null/common cytokine receptor chain γ null double mutant mice, IL-15 null mice) have been studied during pregnancy. Genetic deficiency of uterine NK cells causes a lack of remodeling of the uterine vasculature resulting in hypertrophied vascular media, swollen endothelial cells, and narrow vessel lumens (Ashkar and Croy, 2001; Barber and Pollard, 2003; Croy et al., 2002; Guimond et al., 1997). NK cell-mediated effects on the uterine vasculature may be directed by NK cell production of an assortment of angiogenic growth factors, including vascular endothelial growth factor A (VEGF A) (Hanna et al., 2006; Lash et al., 2006b; Li et al., 2001; Wang et al., 2000) nitric oxide (NO) (Ain and Soares, 2004; Burnett and Hunt, 2000; Burnett et al., 2002; Hunt et al., 1997; Hunt et al., 2000) and pro-inflammatory cytokine interferon γ (IFN γ) (Ashkar et al., 2003; Ashkar et al., 2000; Monk et al., 2005; Murphy et al., 2009).

Uterine NK cell-invasive trophoblast cell interactions

The nature of the interaction between uterine NK cells and trophoblast cells is not clearly understood. At the onset of uterine NK cell recruitment, NK cells are positioned in close contact with growing trophoblast cells (gestation d7.5 to d 9.5; **Fig. 1.4**). As gestation proceeds, NK cells exit the decidua. By gestation d13.5 NK cells are numerous and are concentrated in the metrial gland region. As gestation proceeds further, uterine NK cell number decreases. The movement of invasive trophoblast cells into the metrial gland is initiated as NK cell numbers decrease. A reciprocal relationship exists in rat and mouse between the disappearance of the NK cells and initiation of trophoblast invasion (Ain et al., 2003a).

Fig. 1.4. Natural killer cell, uterine spiral artery, and trophoblast cell dynamics within rat placentation sites throughout gestation. The schematic diagram highlights the reciprocal relationship between the uterine natural killer cells and the invasive trophoblast cells through different time-points of gestation. Two waves of uterine spiral artery remodeling are executed through the actions of natural killer cells (first wave) and invasive trophoblast cells (second wave).

This reciprocal relationship is also supported by observations with an NK deficient mouse model (Ain et al., 2003a). Trophoblast cell invasion has been investigated in wild type and in Tg ϵ 26 transgenic (deficient in NK cells) mice. Pregnant Tg ϵ 26 transgenic mice possess very few NK cells in their mesometrial decidua and metrial gland on gestation d12.5, in contrast to the large number of NK cells in these compartments of the wild type mouse. NK cell deficiency is correlated with an accelerated migration of cytokeratin-positive trophoblast cells into the mesometrial decidua. This observation contrasted with minimal trophoblast cell invasion in wild type mice on gestation d12.5.

The reciprocal relationship between NK cells and invasive trophoblast cells is further demonstrated in the Brown Norway (BN) rat strain (Konno et al., 2007). The late gestation invasion of trophoblast cells into the metrial gland of BN rats is decreased in comparison to other strains. The decreased trophoblast invasion is associated with a prominent retention of NK cells. The retained NK cells are prominently arranged in close proximity to the uterine mesometrial vasculature of the late gestation stage placentation site.

Evidence exists that human uterine NK cells may be the source of regulatory molecules that may promote (e.g. IL8, IP10) (Hanna et al., 2006; Hanna and Mandelboim, 2007) or inhibit (e.g. IFN γ) trophoblast cell invasion (Ain et al., 2003a; Hu et al., 2006b; Hu et al., 2008; Lash et al., 2006a). NK cells may have a direct effect on trophoblast cells or alternatively indirect effects via actions on other constituents of the uterine mesometrial compartment. The latter may include uterine NK cell products targeting the uterine mesometrial endothelium, which represent the guidance system for the movement of invasive endovascular trophoblast cells.

Hypoxia and HIF signaling

Hypoxia is defined as a condition of reduced oxygen pressure below a critical threshold which brings about restriction of proper functioning of organs, tissues or cells (Hockel and Vaupel, 2001). The concept of hypoxia is context dependent. Normoxic conditions for embryonic or adult cells vary between 2-9% of oxygen. Certain regions in thymus, medulla of kidney and bone marrow can exist in as low as 1% oxygen due to their specialized, atypical vascular networks (Simon and Keith, 2008). Early embryonic development takes place in low oxygen (1-2%). Balance in oxygen levels is maintained by cells primarily through induction of specialized transcription factors known as hypoxia inducible factors (HIFs).

HIFs are basic Per-Arnt/AhR-Sim basic helix loop helix (bHLH-PAS) transcription factors (Gu et al., 2000). The HIFs form heterodimers with aryl hydrocarbon receptor nuclear translocator (ARNT); also known as HIF1 β and bind to specific DNA sequences known as hypoxia responsive elements (HREs) which are located in the promoter, introns and 3' enhancers of a large number of oxygen regulated target genes (Wang et al., 1995; Wang and Semenza, 1995). Three separate genes code for HIF1 α , HIF2 α and HIF3 α . HIF1 α is ubiquitously expressed, whereas HIF2 α and HIF3 α show more tissue specific expression (Wiesener et al., 2003). HIF3 α has multiple splice variants (Gu et al., 1998).

HIF α subunits are regulated by oxygen tension, whereas the ARNT subunit is insensitive to changes in oxygen concentration (**Fig. 1.5**). Under normoxic conditions HIF α subunits are hydroxylated on two conserved proline residues, P402 and P564 (Ivan et al., 2001; Jaakkola et al., 2001a) by a family of three prolyl hydroxylases (PHD1, PHD2 and PHD3) (Bruick and McKnight, 2001; Epstein et al., 2001). Hydroxylated HIF α proteins are degraded by mechanisms

involving von Hippel Lindau (pVHL) tumour suppressor proteins, which covalently tag HIF proteins with polyubiquitin and lead them to proteasome mediated degradation (Schofield and Ratcliffe, 2004). Under hypoxic conditions HIF α proteins are not hydroxylated and are therefore not degraded (Simon and Keith, 2008). The accumulated HIF α proteins translocate into the nucleus where they dimerize with ARNT and bind to the HREs (RCGTG motif where R is any purine residue). The heterodimer further binds to a transcriptional coactivator, CREB binding protein (CBP)/ p300, for full functional activation of HIF signaling (Ema et al., 1999). Downstream target genes of HIF signaling are stress response gene families such as glucose transporters, glycolytic enzymes, angiogenic factors, hematopoietic growth factors and gene families which affect cell growth, survival and motility (Schofield and Ratcliffe, 2004; Semenza, 2000, 2001).

Hypoxia signaling and trophoblast cell development

Oxygen is an essential nutrient for cells. Oxygen is delivered to tissues via red blood cells through the vasculature. Molecular mechanisms mediating cellular responses to low oxygen tension have been identified. HIFs are activated by low oxygen and promote transcriptional regulation of downstream effector genes, which lead to cellular adaptations to hypoxia (Wang et al., 1995; Wang and Semenza, 1995).

Placental and fetal development rely on oxygen availability. Uterine oxygen concentrations are low (1-2%) before chorioallantoic placenta formation (Rodesch et al., 1992). Before gestation d9.5, the mouse embryo is heavily dependent on glycolysis for ATP generation (Simon and Keith, 2008). However, by gestation d10.5-d11.5, establishment of placental circulation increases intrauterine oxygen concentrations. Once the hemochorial placenta is

established, oxygen concentrations increase to approximately 8%. *In vitro* studies demonstrated that low oxygen tension can modulate trophoblast differentiation (Adelman et al., 2000; Alsat et al., 1996; Caniggia et al., 2000; Genbacev et al., 1996; James et al., 2006a, b; Jiang et al., 2000; Nelson et al., 1999). An oxygen gradient has also been proposed to be the primary effector regulating gestation dependent vascular remodeling (Burton and Jauniaux, 2001; Caniggia et al., 2000; Fryer and Simon, 2006; Genbacev et al., 1996). Mutagenesis of components of HIF signaling in mice (Arnt, Vhl, Phd2, HIF1 α and HIF2 α) results in aberrant placental phenotypes and disruptions in trophoblast lineage commitment (Adelman et al., 2000; Cowden Dahl et al., 2005; Gnarr et al., 1997; Maltepe et al., 2005; Takeda et al., 2006). An appropriate balance between trophoblast proliferation and differentiation is required to produce a functional placenta (Fryer and Simon, 2006).

Oxygen concentration and trophoblast cell invasion

Low oxygen tension or exposure of trophoblast cells to gradients of oxygen concentrations have been shown to both activate and inhibit trophoblast invasion (Caniggia et al., 2000; Crocker et al., 2005; Genbacev et al., 1996; Graham et al., 2000; Hayashi et al., 2005; James et al., 2006a, b; Kadyrov et al., 2003; Kilburn et al., 2000; Robins et al., 2007; Rosario et al., 2008; Zhou et al., 1997). These studies have used different experimental procedures, cell types, duration and concentration of oxygen exposure. A study looked at the effects of low oxygen tension on four different transformed trophoblast cell lines; HTR-8/SVneo, SGHPL-4, JEG3 and JAR (Lash et al., 2007). These cell populations exhibited pronounced differences in the extent of invasiveness upon exposure to low oxygen tensions (3%).

Fig. 1.5. Schematic of the hypoxia inducible factor (HIF) signaling pathway. The HIFs form heterodimers with aryl hydrocarbon receptor nuclear translocator (ARNT); also known as HIF1 β and bind to specific DNA sequences known as hypoxia responsive elements (HREs) which are located in the promoter, introns and 3' enhancers of a large number of oxygen regulated target genes. HIF α subunits are regulated by oxygen tension, whereas the ARNT subunit is insensitive to changes in oxygen concentration.

The impact of oxygen tension on development of invasive trophoblast lineages from trophoblast stem cell populations has received little attention. Our laboratory has identified two reproducible *in vivo* methods for perturbing the development of the placentation site (Ain et al., 2004; Alam et al., 2007; Ho-Chen et al., 2006; Ho-Chen et al., 2007; Rosario et al., 2008); see Preliminary Data). Exposure of pregnant rats to hypobaric-hypoxia during the establishment of the placenta (gestation d6.5 to d13.5) or NK cell depletion during the same phase of pregnancy results in profound structural changes: 1) activation of intrauterine endovascular trophoblast invasion; 2) alteration in chorioallantoic placental organization (Rosario et al., 2008;summarized in Fig. 4).

Hypoxia activation of epigenetic regulators

Hypoxia signaling mediated by HIF transcription factors are known to modulate adaptations by epigenetic regulators. Regulation of histone methylation by low oxygen signaling is an area of active research. Although it has been observed that under low oxygen exposure (0.2%) hypoxia promotes increase in H3K9 trimethylation marks and global deacetylation, promoters of hypoxia regulated genes have been shown to have increased H3K4 tri-methylation and decreased H3K27 trimethylation (Johnson et al., 2008).

Under low oxygen, stabilized HIF transcription factors increase their repertoire of downstream players by regulating chromatin modifiers which then are targeted to different regulatory regions and control cellular adaptations to low oxygen. So apart from transcriptional regulation, epigenetic regulation is another rapid regulatory device that the cells utilize to adapt to low oxygen environment. Histone lysine demethylases consists of two different groups: flavin adenine dinucleotide (FAD)-dependent enzyme and the Jmjc domain containing demethylases

(Mosammaparast and Shi, 2010). Jmjc domain containing demethylases are dioxygenases whose activities require Fe(II), α -ketoglutarate, and oxygen. There are 30 known jmjc domain containing proteins out of which some are hypoxia responsive (Pollard et al., 2008). Based on gene expression analysis, it has been identified that JMJD1A, JMJD2B as well as JMJD1B, JMJD2C, JMJD6, PLU-1, SMCX, RBP2, and KIAA1718, could be upregulated by hypoxia (Yang et al., 2009). ChIP seq studies in human cell lines have identified several JmJc family members which are direct targets of HIF transcription factors which include PLU-1, JMJD1A, JMJD2B, JMJD2C (Yang et al., 2009).

Epigenetics, Hypoxia and Cell invasion

Hypoxia signaling through HIF transcription factors upregulate a number of JmJc domain containing proteins, out of which a subset of them are involved in cell invasion particularly in cancer cell metastases. *Jmjd2c* or *Kdm4c* has long been shown to be amplified in different types of cancers like squamous cell carcinoma, medulloblastoma and in prostate carcinomas. In colorectal cancer (CRC) cells, *Jmjd2c* is upregulated on hypoxia exposure and regulates cell proliferation, apoptosis, cell cycle arrest and invasion. JMJD2B was overexpressed in CRC tissues and had positive correlation with deeper depth of invasion and advanced clinical stages (Fu et al., 2012).

Recently, the mechanism of *Jmjd2c* mediated regulation of invasion and metastasis has been shown in breast cancer cells (Luo et al., 2012). JMJD2C interact with HIF1A and is preferentially recruited to the response elements of a subset of hypoxia responsive genes involved in metabolic switch and metastatic invasion in lung cancer cells. Disruption of *Jmjd2c*

significantly downregulated metastasis and also caused reduction of tumor growth in a mouse model.

Epigenetically altered VHL-HIF pathway has been implicated in metastatic pathology of clear cell renal carcinoma (Vanharanta et al., 2013). Studying two pro metastatic VHL-HIF targets CXCR4 and CYTIP genes, the authors show that that loss of Polycomb repressive complex 2 (PRC2)-dependent histone H3 Lys27 trimethylation (H3K27me3) upregulates HIF-driven chemokine (C-X-C motif) receptor 4 (CXCR4) expression, promoting chemotactic cell invasion. Loss of promoter DNA methylation resulted in upregulation of HIF target CYTIP gene. Results from the study elucidate a clear mechanism of HIF driven epigenetic amplification of tumor initiating pathways, resulting in tumor metastasis.

Epigenetic regulation of trophoblast cell invasion

Histone deacetylation has been linked to HIF mediated effector functions in other systems. ARNT null TS cells have been shown to have significantly lower HDAC activity characterized by differentiation independent induction of H4acetylation and altered class 2 HDAC subcellular localization. Inhibition of HDAC activity in TS cells mimics the trophoblast differentiation defects observed in ARNT null TS cells implying greater roles of HIF mediated signaling pathway and HDACs in the process of trophoblast differentiation and invasion (Maltepe et al., 2005).

Trophoblast cells show increased invasiveness on differentiation. They undergo epithelial to mesenchymal transition with a marked loss of E-cadherin. Abell et al. very elegantly probe mechanisms underlying this epithelial mesenchymal transition (Abell et al., 2011). MAP3K4 kinase deficient TS cells show increased invasiveness with loss of apical basal polarity, gain of

mesenchymal front-back polarity , significant loss of ecadherin expression and concomitant gain of mesenchymal markers like N-Cadherin and Vimentin. However this acquisition of mesenchymal characteristics do not alter the “stemness” of the trophoblast cells as they can equally contribute to placentas when injected in blastocysts. Histone acetylation has been shown to be a regulator of gene activation. Global loss of histone acetylation has been observed when TS cells differentiate. MAP3K4 regulation of CBP acetyl transferase is pivotal in maintenance of the epithelial phenotype of the trophoblast stem cells.

Research Objectives

During pregnancy, the maternal fetal interface is a dynamic site undergoing pregnancy associated adaptations. Vascular remodeling of the maternal uterine spiral arteries facilitates nutrient flow and gas exchange in the growing fetus represents a critical event in the establishment of the hemochorial placenta. Failure in this process results in unmodified vessels and gives rise to a number of pregnancy associated diseases like preeclampsia (affects 5-7% of all pregnancies), intra uterine growth restriction (IUGR) and pre-term birth. The rat and the human both possess hemochorial placentation and overriding similarities exist between the species, especially in the process wherein trophoblast cells move out of the chorioallantoic placenta and invade into the uterine endometrium and establish intimate relationships with the uterine vasculature (Harris, 2010; Pijnenborg et al., 1981b; Pijnenborg et al., 2006). Uterine NK cells and invasive trophoblast cells have been identified as two key players mediating pregnancy associated vascular changes.

Disrupted oxygen delivery to the fetus retards somatic growth and brain development. In some situations it can also lead to fetal death. NK cells have been implicated in preeclampsia.

Aberrant NK cell number, activation and signaling have been related to failure of pregnancy associated vascular remodeling. Chronic placental hypoxia and altered hypoxia signaling have been proposed to be major players in the pathogenesis of preeclampsia. Thus, understanding the regulation of uterine vascular remodeling and trophoblast invasion is critical in deciphering the molecular mechanisms of the pathogenesis of pregnancy associated disorders.

There are two specific aims in this research project (**Fig. 1.6**), they are:

1. To investigate NK cell regulation of hemochorial placentation
2. To examine epigenetic regulation of TS cell adaptations to hypoxia through activation of KDM3A

Experimental findings related to Specific Aim 1 are presented in Chapter 2 and those associated with Specific Aim 2 are presented in Chapter 3.

Fig. 1.6. Schematic diagram describing the objectives of the research. NK cells regulate uterine vascular development, which impacts oxygen delivery (ΔO_2), activates HIF signaling, and modulates trophoblast lineage development.

CHAPTER 2:

NATURAL KILLER CELL REGULATION OF HEMOCHORIAL PLACENTATION

ABSTRACT

During the establishment of pregnancy, uterine stromal cells differentiate into decidual cells and recruit a population of lymphocytes called natural killer (NK) cells. This process is conserved in laboratory rodents, humans, and other species with hemochorial placentation. NK cells associate with uterine spiral arteries, the conduit for nutrient delivery to the placenta and fetus, and are hypothesized to contribute to the regulation of pregnancy-dependent uterine spiral artery remodeling. Failures in uterine spiral artery remodeling are associated with diseases of pregnancy, such as preeclampsia and intrauterine growth restriction. This prompted an investigation of NK cells as potential regulators of hemochorial placentation. NK cell depletion within the uterus decreased the delivery of pro-angiogenic factors and delayed uterine spiral artery development leading to decreased oxygen tension at the placentation site, stabilized hypoxia inducible factor (HIF) 1A protein within the primordial placenta, and re-directed trophoblast cell differentiation to junctional zone/invasive trophoblast cell lineages. Invasive endovascular trophoblast cells replaced the endothelium of uterine spiral arteries extending the depth of the placental vascular bed and accelerating vessel remodeling. Hypoxia-regulated trophoblast lineage decisions, including expansion of invasive trophoblast cells, could be reproduced *in vitro* using rat trophoblast stem cells; and were dependent on hypoxia-inducible factor signaling. We conclude that NK cells guide hemochorial placentation through controlling a hypoxia-sensitive adaptive reflex regulating trophoblast lineage decisions.

INTRODUCTION

Hemochorial placentation is shared by many mammalian species, including humans, some nonhuman primates and rodents (Davies and Glasser, 1968; Enders and Welsh, 1993; Georgiades et al., 2002). The hemochorial placenta is organized into two distinct compartments. Each compartment provides a specialized function, which includes: i) delivery of maternal nutrients to the placenta; and ii) transfer of nutrients from the placenta to the developing fetus. These functionally distinct placental compartments are under different regulatory programs. The maternal-fetal interface is a dynamic site undergoing pregnancy-associated adaptations (Enders and Welsh, 1993). A critical adaptation is the extensive vascular remodeling of the maternal uterine spiral arteries, which facilitates nutrient flow and gas exchange with the growing fetus (Adamson et al., 2002; Kaufmann et al., 2003; Pijnenborg et al., 2006; Red-Horse et al., 2004). Failures in this process result in unmodified vessels and give rise to pregnancy-associated diseases such as preeclampsia, intrauterine growth restriction (IUGR), and pregnancy termination (Kaufmann et al., 2003; Pijnenborg et al., 2006; Redman and Sargent, 2005). The mechanisms controlling uterine vascular remodeling are poorly understood. Putative regulators include natural killer (NK) cells and a specialized lineage of trophoblast cells referred to as invasive or extravillous trophoblast (Croy et al., 2003; Moffett and Loke, 2006a; Pijnenborg et al., 2006).

Uterine adaptations to pregnancy include highly regulated immune cell trafficking (Croy et al., 2003; Erlebacher, 2010; Hunt et al., 2000). Following embryo implantation most leukocytes are excluded from uterine tissue proximal to the placentation site except for NK cells, a process evident in rodents and primates (Bulmer et al., 2010; Croy et al., 2003; Moffett and Loke, 2006a; Zhang et al., 2011). Implantation associated decidualization in the rat and mouse,

results in the accumulation of NK cell numbers in the uterine mesometrial decidua (Ain et al., 2003a; Croy et al., 2003; Zhang et al., 2011). NK cells have been implicated in pregnancy-associated uterine vascular development (Croy et al., 2003; Lash et al., 2010; Smith et al., 2009; Zhang et al., 2011). Genetic deficiency of uterine NK cells results in a lack of remodeling of the uterine vasculature resulting in hypertrophied vascular media, swollen endothelial cells, and narrow vessel lumens (Ashkar and Croy, 2001; Barber and Pollard, 2003; Guimond et al., 1997). NK cell-mediated effects on the uterine vasculature may be directed by NK cell production of an assortment of angiogenic growth factors and vasoactive molecules (Hanna et al., 2006; Hunt et al., 2000; Kalkunte et al., 2009; Lash et al., 2006a; Li et al., 2001; Monk et al., 2005; Wang et al., 2003; Wang et al., 2000). Aberrant NK cell number, activation, and signaling have been implicated in pregnancy complications (Dosiou and Giudice, 2005; Lash and Bulmer, 2011; Trowsdale and Moffett, 2008; Zhang et al., 2011).

The invasive trophoblast lineage arises from trophoblast stem (TS) cells through an as yet unknown differentiation process (Roberts and Fisher, 2011). This differentiated cell lineage possesses a unique gene expression profile and is specialized for adhesion, degradation, and migration through uterine stromal extracellular matrices and restructuring uterine spiral arteries (Ain et al., 2003a; Apps et al., 2011; Bilban et al., 2010; Harris, 2010; Red-Horse et al., 2004). Invasive trophoblast cells take two routes as they penetrate into the uterus. They move between spiral arteries (interstitial invasive trophoblast) or alternatively they move within spiral arteries, replacing the endothelium and in some instances acquiring a pseudo-endothelial phenotype as they proceed (Damsky and Fisher, 1998; Pijnenborg et al., 2006; Red-Horse et al., 2004; Zhou et al., 1997). Rat and human placentation sites exhibit deep intrauterine trophoblast cell invasion (Ain et al., 2003a; Caluwaerts et al., 2005; Kaufmann et al., 2003; Pijnenborg et al.,

2006; Vercruysse et al., 2006), which contrasts with mouse placentation (Adamson et al., 2002; Ain et al., 2003a; Coan et al., 2006). Shallow trophoblast invasion is linked to poor spiral artery remodeling and diseases of pregnancy (Kaufmann et al., 2003; Red-Horse et al., 2004; Whitley and Cartwright, 2010).

A potential interaction between uterine NK cells and trophoblast cells is not clearly understood. A reciprocal relationship exists in rat and mouse regarding the presence of NK cells and invasive trophoblast cells within the uterine mesometrial compartment (Ain et al., 2003a; Konno et al., 2007). NK cells represent effectors directing the first wave of vascular modification. Their disappearance after midgestation marks the entry of invasive trophoblast cells and initiation of the second wave of vascular modification. The reciprocal relationship of NK cells and trophoblast cells is also supported by observations with an NK deficient mouse model (Ain et al., 2003a) and the Brown Norway rat (Konno et al., 2007). NK cells may directly act on trophoblast cells (Ain et al., 2003a; De Oliveira et al., 2010; Hanna et al., 2006; Hu et al., 2006b; Hu et al., 2010) or alternatively they may possess indirect effects on trophoblast cells via actions on other constituents of the uterine mesometrial compartment (Hanna and Mandelboim, 2007; Zhang et al., 2011). The latter may include uterine NK cell products targeting uterine spiral arteries and their delivery of nutrients, including oxygen to the developing placenta.

Placental development is sensitive to oxygen availability. Oxygen tension at the maternal-fetal interface changes with gestation and is affected by placentation (Burton, 2009; Caniggia et al., 2000; Cartwright et al., 2007; Fryer and Simon, 2006; Genbacev et al., 1997). Oxygen tensions tend to be lower during early pregnancy and increase following the establishment of the hemochorial placenta (Fischer and Bavister, 1993; Rodesch et al., 1992; Zamudio, 2003). Insights about the role of oxygen as an intrinsic regulator of placentation have

been derived from mutagenesis of genes in the mouse genome controlling cellular responses to hypoxia. Central to the cellular response to hypoxia is a transcription factor complex referred to as hypoxia inducible factor (HIF; (Dunwoodie, 2009; Majmundar et al., 2010; Semenza, 2010)). Phenotypes of placentas with null mutations for several genes encoding components of the HIF signaling pathway are associated with failures in placentation, including the HIF1A, HIF2A, HIF1B (dimerization partner for HIF1A and HIF2A), prolyl hydroxylase domain protein 2 (PHD2; also known as EGLN1), and von Hippel-Lindau genes (Adelman et al., 2000; Cowden Dahl et al., 2005; Gnarra et al., 1997; Maltepe et al., 2005; Takeda et al., 2006). Exposure of pregnant rats to a hypoxic environment leads to alterations in placentation, especially expansion of the invasive trophoblast lineage (Rosario et al., 2008). This is a conserved adaptive response. Maternal anemia (human) and chronic constriction of the lower aorta (rhesus monkey), which lead to hypoxia at the maternal-fetal interface, are also triggers for increasing intrauterine trophoblast invasion (Kadyrov et al., 2003; Zhou et al., 1993).

In this study, we investigated the role of NK cells on placentation in the rat. Depletion of NK cells affected uterine spiral artery development, oxygen delivery, HIF-dependent trophoblast lineage decisions, and trophoblast-directed uterine spiral artery remodeling. The results indicate that NK cells fundamentally contribute to the organization of the hemochorial placentation site.

MATERIALS AND METHODS

Animals and tissue collection

Holtzman Sprague Dowley (HSD) and Dahl Salt Sensitive (DSS) rats were acquired from Harlan Laboratories (Indianapolis, IN). Brown Norway (BN) and Fischer F344 (F344) rats were obtained from Charles River Laboratories (Wilmington, MA). Transgenic rats expressing

enhanced green fluorescence protein (EGFP) driven by a chicken β -actin promoter (chbA-EGFP; (Ikawa et al., 1999)) were obtained from Masaru Okabe (Osaka University, Osaka, Japan) and used to establish a colony. Animals were housed in an environmentally controlled facility with lights on from 0600-2000 h and allowed free access to food and water. Virgin female rats 8-10 weeks of age were cohabited with adult males (>3 months of age) of the same strain. Mating was assessed by inspection of vaginal lavages. The presence of sperm in the vaginal lavage was considered d0.5 of pregnancy.

An immunodepletion strategy was used to ablate NK cells (Barlozzari et al., 1987; Barlozzari et al., 1985; Murphy et al., 2005). Pregnant rats received intraperitoneal injections of anti-asialo GM1 (0.5 ml/injection; Wako Chemicals, Richmond, VA) on gestation d4.5, d6.5, and d9.5. Control pregnant rats received the same volume of normal rabbit serum.

Some pregnant rats were placed in a hypoxic (8.5% oxygen) gas-regulated chamber (BioSpherix, Lacona, NY) from gestation d8.5 to d9.5. Pair-fed and ad libitum-fed pregnant rats exposed to ambient conditions (normoxia) served as controls.

Oxygen tensions at placentation sites were estimated by pimonidazole-protein adduct formation (Pringle et al., 2007; Samoszuk et al., 2004). Gestation d9.5 animals were weighed and injected intraperitoneally with pimonidazole hydrochloride (HypoxyprobeTM-1, HPI Inc.; Burlington, MA) at a concentration of 60mg/kg of body weight and sacrificed 90 min later by cervical dislocation.

Rat placental tissues were collected on gestation d9.5, d11.5, and d13.5. The primordial placental structure at gestation d9.5 is referred to as the ectoplacental cone. At gestation day 13.5, the placenta is comprised of two distinct dissectible compartments: the junctional zone,

which establishes the border with maternal uterine structures; and the labyrinth zone, which represents the interface with the fetus. Placentation site dissections were performed as previously described (Ain et al., 2006). Tissues for histological analysis were frozen in dry-ice cooled heptane and stored at -80°C. Tissue samples for protein or RNA extraction were frozen in liquid nitrogen and stored at -80°C until processed.

The University of Kansas Animal Care and Use Committee approved protocols for the care and use of animals.

Flow cytometry

Dissociated splenocytes were subjected to density gradient centrifugation with Ficoll Hypaque solution (GE Amersham, Piscataway, NJ) for enrichment of lymphocytes. Enriched cell preparations (1×10^6) were labeled with phycoerythrin (PE) conjugated mouse anti-CD161 (BD Pharmingen, San Diego, CA; Cat. No. 555009) and fluorescein (FITC) conjugated mouse anti-CD3 (BD Pharmingen; Cat. No. 554832). Cells were analyzed by flow cytometry with a BD LSRII (BD Biosciences San Jose, CA).

Immunocytochemistry and histochemistry

Immunocytochemical analyses were performed on 10 μ m frozen tissue sections using Histostain-AEC-plus kits (Zymed, San Francisco, CA) or indirect immunofluorescence detection using goat anti-mouse IgG tagged with Alexa 488 (Invitrogen, Carlsbad, CA, Cat. No. A11029; 1:1000 dilution), goat anti-mouse IgG tagged with Alexa 568 (Invitrogen, Cat. No. A11031; 1:400 dilution), or goat anti-rabbit IgG tagged with cyanine 3 (Cy3; Jackson ImmunoResearch Laboratories, West Grove, PA, Cat. No. 111-165-003; 1:250 dilution). Nuclei were visualized with 4',6-diamidino-2-phenylindole (DAPI, Molecular Probes, Carlsbad, CA). Negative controls

were performed with normal rabbit serum or isotype-specific control mouse IgG and did not exhibit positive reactivity in the tissue sections. Processed tissue sections were inspected and images recorded with a Leica MZFLIII stereomicroscope equipped with a charge-coupled device (CCD) camera (Leica, Welzlar, Germany).

Trophoblast cells. Trophoblast cells were detected using a mouse anti-pan cytokeratin antibody (Sigma-Aldrich, St.Louis, MO; Cat. No. C2931) at a dilution of 1:400 (Konno et al., 2007). Immunofluorescence detection was performed with a mouse monoclonal antibody to pan cytokeratin tagged with FITC (Sigma-Aldrich; Cat. No. F3418); and used at a dilution of 1:200.

NK cells. NK cells were detected with antibodies against Perforin (PRF1) and ANK61 antigen. Rabbit anti-rat PRF1 antibodies (Torrey Pines Biolabs, Houston, TX; Cat. No. TP251) were used at a concentration of 2.5 µg/ml. Immunoreactivity was visualized using alkaline phosphatase conjugated goat anti-rabbit immunoglobulin (Sigma-Aldrich; Cat. No. A3687) and nitro blue tetrazolium/bromochloroindoyl phosphate (Hu et al., 2006b). Mouse anti rat ANK61 antibodies (Santa Cruz Biotechnology, Santa Cruz, CA; Cat. No. sc-59340) were used at 1:100 dilution. Uterine NK cells present in the uterine mesometrial compartment specifically bind prolactin-like protein-A (PLP-A; (Muller et al., 1999)). Consequently, we also used a fusion protein containing human placental alkaline phosphatase (AP) and PLP-A (AP-PLP-A) as a ligand for detection of PLP-A binding to uterine NK cells, as previously described (Muller et al., 1999). AP was used as a negative control.

Endothelial cells. Mouse antibodies to a rat platelet/ endothelial cell adhesion molecule1 (PECAM1) (Serotec, Oxford, UK; Cat. No. MCA970) were used to identify endothelial cells (1:20 dilution).

Smooth muscle cells. Smooth muscle cells were monitored with a mouse smooth muscle α actin (ACTA2) antibody (Sigma-Aldrich; Cat. No. A2547) using a dilution of 1:400.

Immunofluorescence detection was performed with mouse monoclonal antibody to ACTA2 tagged with Cy3 (Sigma-Aldrich; Cat. No. C6198); and used at a dilution of 1:300.

Junctional zone trophoblast lineages. TPBPA localizes to junctional zone progenitor cell population and some of its differentiated derivatives (77). Rabbit polyclonal antibodies were generously provided by Dr. Kunio Shiota (University of Tokyo, Japan) and used at a dilution of 1:1000.

Placental compartments. Regions of the placentation sites were determined by vimentin immunostaining. A mouse monoclonal antibody to vimentin (Sigma-Aldrich; Cat. No. V6389) was used at a dilution of 1:500.

HIF1A. HIF1A stabilization was monitored with a mouse anti-HIF1A antibody (BD Biosciences; Cat. No. 610959) and used at a dilution of 1:200.

Pimonidazole-protein adducts. Oxygen tension within placentation sites was estimated by detection of pimonidazole-protein adducts. The 4.3.11.3 mouse monoclonal antibody supplied with the Hypoxyprobe kit (HPI Inc.) was used at a dilution of 1:50.

Western blot analysis

HIF1B and β -actin (ACTB) protein levels were evaluated by western blot analysis. Rat TS cell lysates were prepared in radioimmunoprecipitation assay (RIPA) buffer (10 mM Tris-HCl, pH 7.2, 1% Triton X-100 or 1% Nonidet P-40, 1% sodium deoxycholate, 0.1% SDS, 150 mM NaCl, 5 mM EDTA, 1 mM sodium orthovanadate, 1 mM phenylmethylsulfonyl fluoride, 10

µg/ml aprotinin). Protein concentrations were determined by the DC protein assay (Bio-Rad, Hercules, CA). Proteins were separated by SDS-PAGE and transferred onto nitrocellulose membranes. Immunoreactive proteins were detected with mouse antibodies to HIF1B (BD Pharmingen; Cat. No. 611079; 1:1000 dilution) and ACTB (Sigma-Aldrich; Cat. No. A5228; 1:5000 dilution). Immunoreactive proteins were visualized by enhanced chemiluminescence according to the manufacturer's instructions (Amersham Biosciences, Piscataway, NJ).

qRT-PCR

Total RNA was extracted from cells and tissues using TRIzol reagent (Invitrogen). cDNAs were synthesized from total RNA (1 µg) for each sample using Superscript 2 reverse transcriptase (Invitrogen), diluted five times with water, and subjected to qRT-PCR to estimate mRNA levels. Primers were designed using Beacon primer designer (Applied Biosystems, Foster City, CA). Primer sequences can be found in **Table 1**. Real-time PCR amplification of cDNAs was carried out in a reaction mixture (20 µl) containing SYBR GREEN PCR Master Mix (Applied Biosystems) and primers (250 nM each). Amplification and fluorescence detection were carried out using the ABI Prism 7500 real time PCR system (Applied Biosystems). Cycling conditions included an initial hold step (95 °C for 10 min) and 40 cycles of a two-step PCR (92 °C for 15 sec, then 60 °C for 1 min), followed by a dissociation step (95 °C for 15 sec, 60 °C for 15 sec, and then 95 °C for 15 sec). The comparative cycle threshold method was used for relative quantification of the amount of mRNA for each sample normalized to 18S RNA.

In situ hybridization

Transcripts were localized at placentation sites using nonradioactive in situ hybridization as previously described (Ain et al., 2003a). Ten µm cryosections were prepared and stored at

-80°C until used. A plasmid containing a cDNA for Prl7b1 (Wiemers et al., 2003) was used as a template to synthesize sense and antisense digoxigenin-labeled riboprobes according to the manufacturer's instructions (Roche Molecular Biochemicals, Indianapolis, IN). Tissue sections were air dried and fixed in ice cold 4% paraformaldehyde in phosphate buffered saline. Prehybridization, hybridization, and detection of alkaline phosphatase conjugated anti-digoxigenin were performed as previously reported (Ain et al., 2003b). Images were captured using a Leica MZFLIII stereomicroscope equipped with a Leica CCD camera.

Morphological measurements of placentation sites

Measurements of the depth of trophoblast invasion, the sizes of placental compartments, and blood vessel and uterine mesometrial compartment cross-sectional areas were performed with National Institutes of Health Image J software as previously described (Konno et al., 2007; Rosario et al., 2008). Definitions of each compartment within the rat placentation site (uterine mesometrial compartment, metrial gland, mesometrial deciduum, junctional zone, and labyrinth zone) have been described (Ain et al., 2006).

VEGFA protein measurements

VEGFA was measured in decidual lysates by enzyme-linked immunosorbent assay (ELISA) according to the manufacturer's (RayBiotech Inc., Norcross, GA) instructions. Gestation d9.5 mesometrial decidua samples were dissected and lysates prepared in extraction buffer provided by the manufacturer. Measurements were normalized to protein concentration.

Rat TS cell culture

Blastocyst-derived rat TS cells (Asanoma et al., 2011) were used to evaluate the effects of low oxygen on trophoblast lineage decisions. TS cells were cultured in Basal Culture Medium [RPMI 1640 (Cellgro, Herndon, VA), 20% fetal bovine serum (FBS; Atlanta Biologicals, Norcross, GA), 100 μ M 2-mercaptoethanol (Sigma), 1 mM sodium pyruvate (Cellgro), 50 μ M penicillin and 50 U/ml streptomycin (Cellgro)] supplemented with 70% rat embryonic fibroblast (REF) conditioned medium, FGF4 (25 ng/ml; Sigma) and heparin (1 mg/ml; Sigma). TS cells maintained in the basal culture medium (stem cell/proliferative state) were exposed to a range of oxygen tensions (0.5 to 2%) and 5% CO₂ using a NAPCO Series 8000WJ incubator (Thermo Scientific, Pittsburgh, PA) for 24 h and then harvested for cell and molecular analyses.

Matrigel invasion assay

The invasive ability of rat TS cells was measured as previously described (Peters et al., 1999). Rat TS cells were placed in Matrigel invasion chambers (BD Biosciences) at a density of 2×10^4 cells per chamber. Cells were allowed to invade for 24 h. Membranes were collected and stained with Diff-Quick (Dade Behring, Newark, DE). Invading cells were visualized by light microscopy and counted.

Short- hairpin RNA (shRNA) constructs and production of lentivirus

Hif1b shRNA constructs in the pLKO.1 vector were obtained from Open Biosystems (Huntsville, AL). Several shRNAs were tested for each gene. The *Hif1b* shRNA sequences used in this analysis are as follows: i) *Hif1b* shRNA-1:

5'GAGAAGTCAGAAGGTCTCTTTTCTCGAGTAAAGAGACCTTCTGACTTCTC3'; ii)

Hif1b shRNA-2:

5'CCAGACAAGCTAACCATCTTACTCGAGTAAGATGGTTAGCTTGTCTGG3'. The control shRNA, which targets no known mammalian gene, pLKO.1-shSCR (Plasmid 1864), was obtained from Addgene (Cambridge, MA) and has the following sequence 5'CCTAAGGTAAAGTCGCCCTCGCTCTAGCGAGGGCGACTTAACCTTAGG3' (Sarbasov et al., 2005b). Third generation lentiviral packaging vectors were purchased from Addgene and included: pMDLg/pRRE (Plasmid 12251), pRSV-Rev (Plasmid 12253) and pMD2.G (Plasmid 12259). Lentiviral particles were produced as previously reported (Lee et al., 2009). In brief, 293FT cells (Invitrogen) were transiently transfected using Lipofectamine 2000 (Invitrogen) with the following plasmids: shRNA containing transducing vector, third-generation packaging system plasmids (pMDLg/pRRE and pRSV-Rev; 104), and a VSVG envelope plasmid (pMD2.G). After transfection, cells were maintained in 50% DMEM with high glucose (Cellgro), 45% Opti-MEM I (Invitrogen) and 5% FBS. Culture supernatants containing lentiviral particles were harvested every 24 h for two to three days. Supernatants were centrifuged to remove cell debris, filter sterilized, concentrated by ultracentrifugation, and stored at -80°C until used.

Statistical analyses

Data analyses were performed using SigmaPlot 11.2 statistical software package (Systat Software, Inc, San Jose, CA). Specific details of the analyses are presented in the figure legends.

RESULTS

Depletion of uterine NK cells

In vivo depletion of NK cells can be achieved by treatment with anti-asialo GM1 antibodies (Barlozzari et al., 1987; Barlozzari et al., 1985; Murphy et al., 2005). HSD rats were

injected intraperitoneally with 500 µl of anti-asialo GM1 antibodies (Wako Chemicals, Richmond, VA) or normal rabbit serum (control) on gestation d4.5 or gestation d4.5 and d9.5. Placentation sites were collected on gestation d9.5 or d13.5 and examined for the presence of NK cells using PRF1 immunostaining. A single injection of anti-asialo GM1 at gestation d4.5 depleted NK cells from placentation sites at gestation day 9.5 (**Fig. 2.1 A-F**) and decreased uterine NK cell numbers on gestation d13.5, indicating evidence of recovery (**Fig. 2.2 A**). A combination of two injections of anti-asialo GM1 (one at gestation d4.5 and the second at d9.5) was effective in depleting uterine NK cells at gestation d13.5 (**Fig. 2G-L**). qRT-PCR analysis of d9.5 uterine mesometrial decidua for *Prf1* mRNA verified the depletion of NK cells (Fig. 1.2 B). Successful NK cell depletion was confirmed through the use of other strategies to detect NK cells (ANK61 immunostaining and AP-PLP-A binding; **Fig. 2.3**). The immunodepletion treatment was also effective in depleting systemic NK cells as assessed by flow cytometric analysis of splenocytes with NK1.1 antibodies (also known as NKRP1 or CD161; **Fig. 2.4**). Controls exhibited the expected full complement of systemic and uterine NK cells. Delaying the initiation of anti-asialo GM1 antibody treatment until gestation d6.5 was less effective in depleting NK cells (**Fig. 1.5**). Thus, we have a protocol for preventing the colonization of the placentation site with NK cells and a tool for investigating the role of NK cells on hemochorial placentation.

NK cells, endovascular trophoblast invasion, and uterine spiral artery remodeling

The placentation site at gestation d13.5 is well defined but lacks penetration of invasive trophoblast cells beyond the decidual compartment (Ain et al., 2003a). In contrast, gestation d13.5 placentation sites from NK cell depleted rats exhibited distinct changes in their placental

Fig. 2.1 NK cell depletion from d9.5 and d13.5 placentation sites. **A)** Rats were treated on gestation d4.5 with normal rabbit serum (Control) or anti-asialo GM1 on gestation d4.5 (Anti-aGM1-1_(4.5)) and sacrificed on gestation d9.5. This treatment strategy effectively depleted NK cells from placentation sites on gestation d9.5 (**B-F**). **D and E** are high magnification images of boxed regions in **B and C**, respectively. **G)** Rats were treated on gestation d4.5 and d9.5 with normal rabbit serum (Control) or anti-asialo GM1 (Anti-aGM1-2_(4.5, 9.5)) and sacrificed on gestation d13.5. This treatment strategy effectively depleted NK cells from placentation sites on gestation d13.5 (**H-L**). **J and K** are high magnification images of boxed regions in **H and I**, respectively. NK cells were identified using PRF1 immunocytochemistry. Quantification of relative depletion (% of control) is shown in panels **F** (n=6 per group, P<0.02; Mann-Whitney Rank Sum Test) and **L** (n=5 per group, P<0.001; Student's *t*-test). Scale bars=0.25mm.

Fig. 2.2. NK cell numbers in gestation d13.5 placentation sites following a single injection of anti-asialo GM1 on gestation d4.5. **A)** Rats were treated on gestation d4.5 with a single dose of normal rabbit serum (Control) or antiasialo GM1 (Anti-aGM1-1_(4.5)) and sacrificed on gestation d13.5. This treatment strategy significantly decreased NK cell numbers but did not eliminate them from the placentation site on gestation d13.5 (**B-F**). **D and E** are high magnification images of boxed regions in **B and C**, respectively. NK cells were identified using PRF1 immunocytochemistry. **F)** Quantification of PRF1 positive cells (number/mm²; n=5 per group). Asterisks indicate significant differences from controls (n=5 per group, P<0.01; Mann-Whitney Rank Sum Test). Scale bars=0.25 mm. **G)** *Prfl* transcript levels in gestation d9.5 decidual tissues dissected from rats treated on gestation d4.5 with normal rabbit serum (Control) or anti-asialo GM-1 (anti-aGM1-1_(4.5)). *Prfl* transcript levels were measured by qRT-PCR (SYBR Green, $\Delta\Delta$ CT method). 18S rRNA served as an internal control. Asterisks indicate significant differences (Control, n=5 and anti-aGM1- 1_(4.5), n=5; P<0.05, Mann-Whitney Rank Sum Test).

G

vascular beds, including deep intrauterine endovascular trophoblast invasion (**Fig. 2.6**). Uterine spiral arteries were lined with cuboidal-shaped cells, which stained positive for cytokeratin (**Fig. 2.6 B and D**) and expressed prolactin family 7, subfamily b, member 1 (*Pr17b1*; also known as prolactin-like protein-N) mRNA (**Fig. 2.6 F and G**). *Pr17b1* transcripts are restricted to the invasive trophoblast cell lineage (Konno et al., 2007; Rosario et al., 2008; Wiemers et al., 2003). The effects of NK cell depletion on placentation were not unique to the HSD rat. Three additional inbred strains (BN; DSS; F344) showed similar increases in endovascular trophoblast invasion following NK cell depletion (**Fig. 2.7**). We also verified the extraembryonic origin of the endovascular invasive trophoblast cells using a transgenic rat model expressing enhanced green fluorescent protein (EGFP) under the control of the chicken β -actin promoter (chbA-EGFP; (Ikawa et al., 1999; Rosario et al., 2008). NK cell depletion similarly stimulated EGFP-expressing extraembryonic cells to invade into the uterine vasculature of wild-type HSD females (**Fig. 2.6 J**). As indicated above, a single injection of anti-asialo GM1 on gestation d4.5 depleted NK cells at d9.5 with some recovery by d13.5 (**Fig. 2.2**). This treatment strategy was effective in stimulating endovascular trophoblast cell invasion on d13.5 (**Fig. 2.8**), suggesting that NK cell depletion was not required throughout the eight-day interval. Delaying the initiation of anti-asialo GM1 treatment until gestation d6.5 did not effectively deplete uterine NK cells (**Fig. 2.5**) nor did it promote endovascular trophoblast invasion (**Fig. 2.8**).

Additional insights into the role of NK cells and endovascular trophoblast in uterine spiral artery remodeling were obtained through immunohistological analysis. Three types of centrally located uterine spiral arteries were observed at gestation d13.5: i) vessels surrounded by NK cells; ii) vessels devoid of NK cells; iii) vessels devoid of NK cells but containing endovascular trophoblast cells. The presence of NK cells led to disruptions in the integrity of the

Fig 2.6 NK cell depletion leads to activation of endovascular trophoblast invasion on gestation d13.5. Rats were treated on gestation d4.5 and d9.5 with normal rabbit serum (Control) or anti-asialo GM1 (NK cell depleted) and sacrificed on gestation d13.5. Invasive endovascular trophoblast cells were identified by pan cytokeratin immunocytochemistry (**A-D**). **E**) Quantification of the depth of cytokeratin positive cell penetration into the uterine mesometrial vasculature. Values are means \pm the standard error of each mean. **Invasion index** = Distance of endovascular cytokeratin positive cell location relative to the trophoblast giant cell layer of the chorioallantoic placenta \div Total distance from the trophoblast giant cell layer to the mesometrial surface of the uterus. The asterisk indicates a significant difference between Control and NK cell depleted (n=5 per group; $P < 0.001$; Student's *t*-test). **F and G**) In situ hybridization of *Prl7b1* mRNA in control and NK cell depleted d13.5 placentation sites. **H**) *Prl7b1* transcript levels in gestation d13.5 metrial gland tissues dissected from control and NK cell depleted rats. *Prl7b1* transcript levels were measured by qRT-PCR (SYBR Green, $\Delta\Delta CT$ method). 18S rRNA served as an internal control. The asterisk indicates a significant difference between Control and NK cell depleted (n=4; $P < 0.001$; Student's *t*-test). **I and J**) Representative images showing EGFP expressing endovascular trophoblast cells at gestation d13.5 placentation sites of Control (**I**) and NK cell depleted (**J**) wild-type female rats mated to ch β A-EGFP transgenic male rats. Please note that NK cell depletion stimulated the invasion of EGFP-positive trophoblast cells into the maternal uterine vasculature. Scale bars=0.25 mm.

Fig. 2.7. NK cell depletion leads to activation of endovascular trophoblast invasion on gestation d13.5 in F344, DSS, and BN inbred rat strains. **A)** Schematic representation of treatments on gestation d4.5 and d9.5 and sacrifice on gestation d13.5. Rats were treated with normal rabbit serum (Control: **B**, F344; **D**, DSS; **F**, BN) or anti-asialo GM1 (NK cell depleted: **C**, F344; **E**, DSS; **G**, BN). Invasive endovascular trophoblast cells were identified by pan-cytokeratin immunocytochemistry. **H-J)** Quantification of the depth of cytokeratin positive cell penetration into the uterine mesometrial vasculature (**H**, F344; **I**, DSS; **J**, BN). Values are means \pm the standard error of each mean. Asterisks indicate significant differences between Control and NK cell depleted ($P < 0.001$; Student's *t*-test).

Fig 2.8 Effects of single injections of anti-asialo GM1 on endovascular trophoblast invasion on gestation d13.5. **A)** Schematic representation of treatment on gestation d4.5 and sacrifice on gestation d13.5. **B)** Schematic representation of treatment on gestation d6.5 and sacrifice on gestation d13.5. Rats were treated with normal rabbit serum (Control: **C**) or anti-asialo GM1 (AntiaGM1-1_(4.5): **D**; Anti-aGM1-1_(6.5): **E**). Invasive endovascular trophoblast cells were identified by pan-cytokeratin immunocytochemistry. **F)** Quantification of the depth of cytokeratin positive cell penetration into the uterine mesometrial vasculature. Values are means \pm the standard error of each mean. The Invasion Index is described in **Fig. 2**. Asterisks indicate significant differences between Control and anti GM1 treated rats (n=5 per group; P<0.001; analysis of variance with Holm-Sidak method for comparisons).

smooth muscle layer surrounding spiral arteries (**Fig. 2.9A and C**). These modifications were not observed in spiral arteries devoid of NK cells (**Fig. 2.9B**). The endovascular trophoblast-bearing (cytokeratin positive) uterine spiral arteries of NK cell depleted rats exhibited additional changes (**Fig. 2.9 D**). These vessels contained diminished ACTA2 and in many instances complete loss of the smooth muscle layer. PECAM 1 immunostaining was absent from some modified uterine spiral arteries, reflecting the disappearance of the endothelium (**Fig. 2.9F**), but present in others containing endovascular trophoblast (**Fig. 2.9 G**) indicative of their acquisition of a pseudo-endothelial phenotype (Damsky and Fisher, 1998; Zhou et al., 1997). Trophoblast cells are proposed to activate endothelial cell apoptosis (Ashton et al., 2005; Red-Horse et al., 2006). NK cells reappear in the uterine mesometrial compartment in rats receiving a single injection of anti-asialo GM1 on gestation d4.5 but not in rats receiving injections on both gestation d4.5 and d9.5 (**Fig. 2.1, Fig. 2.2**). The pseudo-endothelial trophoblast phenotype was much easier to identify following the latter treatment (**Fig. 2.9 G**). Partial and complete NK cell depletion result in distinct endovascular trophoblast phenotypes on gestation d13.5 and suggest that NK cells may modulate the appearance of the pseudo-endothelial phenotype.

Collectively, the results indicate that NK cells regulate uterine spiral artery remodeling through several mechanisms, including: i) through direct actions on the smooth muscle tunica media; ii) via restraining endovascular trophoblast invasion; iii) by modulating the endovascular trophoblast cell phenotype.

NK cells modulate uterine spiral arteries and oxygen delivery

The effects of NK cell depletion on placentation closely resembled our earlier observations on the effects of maternal hypoxia on placentation (Rosario et al., 2008). Maternal

Fig. 2.9. NK cells and endovascular trophoblast cells contribute to remodeling uterine spiral artery structure. Rats were treated on gestation d4.5 and d9.5 with normal rabbit serum (Control) or anti-asialo GM1 (NK cell depleted) and sacrificed on gestation d13.5. Double immunofluorescence staining for ANK61 and ACTA (**A and B**) and cytokeratin and ACTA2 (**C and D**) on representative uterine mesometrial regions are shown. **A and C**) Asterisks demarcate blood vessels possessing interruptions (arrowheads) in the tunica media. **B**) Asterisks identify blood vessels with intact tunica media. In panels **E-G**, rats were treated on d4.5 and d9.5 with normal rabbit serum (Control, **E**) or anti-asialo GM1 (Anti aGM1-1_(4.5), **F**; aGM1-2_(4.5,9.5), **G**). Double immunofluorescence staining for cytokeratin and PECAM1 (**E-G**) on representative uterine mesometrial regions are shown. **G**) The asterisk indicates the location of a blood vessel lined by cells doubly positive for cytokeratin and PECAM1 (yellow). Scale bars=0.25 mm.

hypoxia activates endovascular trophoblast invasion, uterine spiral artery remodeling, and placental reorganization. A 24 h interval of sensitivity to maternal hypoxia was noted between gestation d8.5 and d9.5 (Rosario et al., 2008). This prompted an investigation of NK cell depleted and control placentation sites at gestation d9.5. A prominent difference in the distribution of uterine spiral arteries (detected by ACTA2 and PECAM1 immunostaining) was observed at gestation d9.5 (**Fig. 2.10 A-D**). NK cell depleted placentation sites showed significantly less development of uterine spiral arteries, especially their progression toward developing trophoblast (ectoplacental cone). The difference in vascular development between control and NK cell depleted was not evident by gestation d11.5 (**Fig. 2.11**). Since uterine NK cells are potential sources of angiogenic factors such as vascular/endothelial growth factors (VEGFs; (Kalkunte et al., 2009; Lash et al., 2006b; Li et al., 2001; Wang et al., 2003; Wang et al., 2000)), we investigated *Vegf* transcript and VEGFA protein concentrations in the mesometrial compartment where NK cells normally reside. Transcript levels for *Vegfa*, *Vegfb*, and *Vegfc* and VEGFA protein concentrations were all significantly lower in the NK cell depleted rats. Decreases in *Vegf* transcripts and VEGFA protein are consistent with poor uterine spiral artery development.

We next investigated whether the attenuated uterine spiral artery development impacted oxygen delivery to the placentation site. Pimonidazole hydrochloride forms adducts with proteins in tissues experiencing low oxygen tensions (<10 mm of Hg). Pimonidazole-protein adducts can be immunohistochemically detected and used for assessment of relative tissue oxygen concentrations (Samoszuk et al., 2004), including murine placentation sites (Pringle et al., 2007). NK cell depletion at the placentation site was associated with an increase in the accumulation of pimonidazole-protein adduct formation and thus indicative of oxygen tensions

Fig. 2.10. NK cells and uterine spiral artery development. Rats were treated on gestation d4.5 with normal rabbit serum (Control) or anti-asialo GM1 (NK cell depleted) and sacrificed on gestation day 9.5. Blood vessels were identified by PECAM1 (**A and B**) and ACTA2 (**C and D**) immunocytochemistry. **E**) Numbers of ACTA2 positive vessels within the uterine mesometrial compartment were quantified. The asterisk indicates significant differences between Control and NK cell depleted (n=5; P<0.001; Student's *t*-test). **F-H**) Transcript levels for *Vegfa* (**F**), *Vegfb* (**G**), and *Vegfc* (**H**) were measured in gestation d9.5 mesometrial decidual tissue dissected from Control and NK cell depleted rats. Transcript levels were measured by qRT-PCR (SYBR Green, $\Delta\Delta$ CT method). 18S rRNA served as an internal control. Asterisks indicate significant differences between Control and NK cell depleted (n=5; P<0.02 for each gene; Mann-Whitney Rank Sum Test). **I**) VEGFA protein levels were measured in gestation d9.5 mesometrial decidual tissue dissected from Control and NK cell depleted rats by ELISA and normalized to protein concentration. The asterisk indicates a significant difference between Control and NK cell depleted tissues (n=10; P<0.05; Mann-Whitney Rank Sum Test).

Fig. 2.11. Role of NK cells on uterine spiral artery development at gestation d11.5. A)

Schematic representation of treatment on gestation d4.5 and d9.5 and sacrifice on gestation d11.5. Rats were treated with normal rabbit serum (Control: **B**) or anti-asialo GM1 (NK cell depleted: **C**). Blood vessels were identified by PECAM1 immunocytochemistry. Please note that uterine spiral arteries are well developed in both Control and NK cell depleted tissues. Scale bars=0.25 mm.

below 10 mm of Hg (**Fig. 2.12 A and B**). These results were suggestive of a local hypoxia but contrary to an earlier report, which failed to observe increased pimonidazole-protein adduct formation at the maternal-fetal interface in mice possessing genetic NK cell deficiencies (Leno-Duran et al., 2010).

Cellular responses to low oxygen are regulated by activation of a hypoxia signaling pathway controlled by specialized transcription factors known as HIFs (Semenza, 2010). HIFs are basic helix-loop-helix Per-Arnt/AhR-Sim (bHLH-PAS) transcription factors (Zhang et al., 2011) and consist of an oxygen-labile α subunit and the aryl hydrocarbon receptor nuclear translocator (ARNT, also known as HIF1B). This heterodimer acts to regulate a number of hypoxia-sensitive target genes (Kanasaki et al., 2008). Activation of a cellular response to low oxygen is associated with stabilization of the HIF1A subunit protein, formation of a heterodimers with HIF1B, and modulation of gene transcription. Consequently, we assessed HIF1A protein in NK cell depleted and control placentation sites on gestation d9.5 using immunocytochemistry. NK cell depletion was associated with stabilization of the HIF1A protein within cells of the ectoplacental cone (**Fig. 2.12 E-H**). These results support the idea that NK cell depletion is leading to activation of the hypoxia-signaling pathway within trophoblast cells of the ectoplacental cone.

Collectively, these experiments indicate that NK cells regulate development of uterine spiral arteries and oxygen delivery to the developing placenta.

NK cells, hypoxia, and trophoblast lineage decisions within the placenta

Maternal hypoxia during the labile period of placental morphogenesis activates invasive trophoblast cells, resulting in formation of a placenta that is adept at uterine vascular

Fig. 2.12 NK cells regulate oxygen tension and stabilization of HIF1A at the d9.5 placental site. Representative images are presented of pimonidazole protein adduct (PIM) immunostaining within d9.5 placental sites from Control (**A**) and NK cell depleted (**B**) rats. Staining was consistently greater in NK cell depleted rat placental sites (n=5 per group). Representative images are shown of cytokeratin (**C and D**) and HIF1A (**E-H**) immunolocalization. Ectoplacental cone regions react positively with antibodies to pan-cytokeratin (**C and D**). The boxed areas in panels **C** and **D** are shown in **E and G** and **F and H**, respectively. Panels **G and H** contain a counterstain with DAPI. HIF1A immunofluorescence was consistently stronger in NK cell depleted rat ectoplacental cone areas (n=5 per group). Scale bars=0.25 mm.

modification; whereas later exposure to hypoxia is entirely ineffective (Rosario et al., 2008). This infers a critical developmental window of sensitivity to low oxygen that impacts trophoblast cell lineage decisions. In the next series of experiments, we compared the effects of NK cell depletion (as described above; **Fig. 2.13A**) and maternal hypoxia (exposure to 8.5% oxygen from gestation d8.5 to d9.5; **Fig. 2.13B**) on the expression of trophoblast cell lineage markers within ectoplacental cone tissues isolated on gestation d9.5. Transcripts for a series of junctional zone-specific trophoblast markers (*Prl3dl*: trophoblast giant cells; *Tpbpa*: junctional zone precursor and differentiated trophoblast; *Prl5a1* and *Prl7b1*: invasive trophoblast) were significantly upregulated, whereas a glycogen cell marker (*Gjb3*) and a labyrinthine trophoblast-specific transcript (*Tfeb*) were not affected (**Fig. 2.13 A and B**). The response was similar in the NK cell depleted and hypoxia exposed tissues. *Tpbpa* is expressed in the earliest cell populations committed to junctional zone trophoblast lineages and many of their descendants (Iwatsuki et al., 2000; Simmons and Cross, 2005). TPBPA protein expressing cells in the ectoplacental cone were also upregulated following NK cell depletion or exposure to maternal hypoxia (**Fig. 2.14**).

The hemochorial placenta is organized into two compartments, which reflect trophoblast interactions with two vascular beds. Trophoblast cells connected to the maternal vasculature specialize in facilitating nutrient flow to the placenta. This compartment is referred to as the junctional zone in the rat and extravillous trophoblast in the human. Invasive trophoblast cells of the rat arise from the junctional zone (Ain et al., 2006; Simmons and Cross, 2005). Trophoblast cells developing in proximity to the fetal vasculature promote nutrient transfer to the fetus and constitute the labyrinth zone in the rat and villous trophoblast in the human. We investigated the organization of gestation d13.5 placentation sites in control and NK cell depleted rats using vimentin immunostaining. This technique permits effective demarcation of junctional (negative)

lineage allocation. **A)** Rats were treated on gestation d4.5 with normal rabbit serum (Control) or anti asialo GM1 (NK cell depleted) and sacrificed on gestation d9.5. **B)** Rats were exposed to 8.5% oxygen for 24 h beginning on d8.5 and sacrificed on gestation d9.5. Gestation d9.5 ectoplacental cone tissues were dissected, RNA extracted, and trophoblast lineage-associated transcripts measured by qRT-PCR. qRT-PCR measurements (SYBR Green) were performed using the $\Delta\Delta CT$ method). 18S rRNA served as an internal control. Asterisks indicate significant differences among groups (n=5; $P < 0.01$ for each gene; Mann-Whitney Rank Sum Test). **C and D)** Effects of NK cells on the organization of the gestation d13.5 chorioallantoic placenta. Rats were treated on gestation d4.5 and d9.5 with normal rabbit serum (Control) or anti-asialo GM1 (NK cell depleted) and sacrificed on gestation d13.5. Placentation sites were sectioned and immunostained for vimentin (labyrinth zone and uterine mesometrial compartment positive, junctional zone negative). **C)** Representative localization of vimentin in placentation sites from controls. **D)** Representative localization of vimentin in placentation sites of NK cell depleted rats. Scale bar = 1 mm. The dashed black lines on panels C and D demarcate the positioning of the junctional zone, relative the underlying labyrinth zone. **E)** Ratio of cross sectional areas for junctional zone versus labyrinth zone from Control (n=5) and NK cell depleted (n=5) placentation sites. Values are means \pm the standard error of each mean. Please note the relative enlargement of the JZ from NK cell depleted placentation sites (asterisk; $P < 0.001$; Student's *t*-test).

Fig.2.14. Role of NK cells and hypoxia on TPBPA protein-positive cell distribution within the ectoplacental cone. **A)** Rats were treated on gestation d4.5 with normal rabbit serum (Control) or anti asialo GM1 (NK cell depleted), or **B)** exposed to 8.5% oxygen for 24 h beginning on d8.5. All animals were sacrificed on gestation d9.5. Representative sections through ectoplacental cones immunostained for cytokeratin (**C-E**), TPBPA (**F-H**), or TPBPA counterstained with DAPI (**I-K**). Sections from ectoplacental cones of Control (**C, F, and I**), NK cell depleted (**D, G, and J**), or 8.5% hypoxia exposed (**E, H, and K**) rats. Scale bars=0.125 mm.

and labyrinth (positive) zones. NK cell depletion resulted in an expansion of the junctional zone (**Fig. 2.13D**). A similar placental response occurs following maternal hypoxia exposure (Rosario et al., 2008). Although the junctional zone expanded following NK cell depletion, junctional zone and labyrinth zone-specific gene expression patterns were similar between NK cell depleted and controls (**Fig. 2.15**).

We conclude from these experiments that NK cells and hypoxia modulate trophoblast cell lineage decisions and organization of the developing placenta.

Hypoxia signaling regulates trophoblast cell lineage decisions

We next determined whether the impact of hypoxia on development of junctional zone-specific trophoblast cell lineages was a direct action on the TS cell population and whether the response was dependent on HIF1B signaling. For these experiments, we utilized TS cells derived from rat blastocysts (Asanoma et al., 2011). We first evaluated the effects of a range of oxygen concentrations (0.5 to 2%) on *Tpbpa* gene expression by TS cells maintained in the stem cell state. A 24 h interval was selected since it is sufficient to elicit *in vivo* trophoblast responses (**Fig.2.13**). An oxygen concentration of 0.5% was a reliable activator of *Tpbpa* gene expression and TPBPA protein accumulation (**Fig.2.17**) and was used in all subsequent experiments. TS cells were exposed to low oxygen for 24 h, harvested, and cellular phenotypes assessed. HIF signaling was disrupted through targeting HIF1B, the binding partner for HIF1A, with specific shRNAs. shRNAs were delivered to TS cells in lentiviral vectors. *Hif1b* shRNAs significantly decreased *Hif1b* mRNA and HIF1B protein levels, whereas control shRNAs showed no significant disruption of HIF1B expression (**Fig. 2.18 A and B**). Transcript concentrations for known hypoxia responsive genes (*Ankrd37*, *Egln1*, and *Bhlhe40*; Benita et al., 2009; Semenza,

gene expression. **(A)** Rats were treated on gestation d4.5 and d9.5 with normal rabbit serum (Control) or anti asialo GM1 (NK cell depleted) and sacrificed on gestation d13.5. Junctional and labyrinth zones were dissected, RNA extracted, and qRT-PCR analyses **(B)** performed on genes expressed in the junctional zone (*Tpbpa*, *Gjb3*, *Prl5a1*, *Prl7b1*) and labyrinth zone (*Tfeb*).

Sample size: n=4 per group. Transcript levels were measured by qRT-PCR (SYBR Green, $\Delta\Delta CT$ method). 18S rRNA served as an internal control.

Fig. 2.16. Effects of low oxygen on TS cell responses. TS cells maintained in stem cell conditions were exposed to low oxygen (0.5%) for 24 h. **A)** qRT-PCR analyses for selected trophoblast cell lineage markers (*Tpbpa*, *Prl3dl*, and *Tfeb*) in TS cells exposed to ambient or low oxygen. qRT-PCR measurements (SYBR Green) were performed using the $\Delta\Delta CT$ method). 18S rRNA served as an internal control. Asterisks indicate significant differences among groups ($P < 0.05$ for each gene; Mann Whitney Rank Sum Test). All experiments were performed in triplicate. **B-E)** Immunofluorescence staining for TPBPA in TS cells exposed to ambient or low oxygen. **F, G)** Assessment of the effects of oxygen tension on TS cell invasion. Cells penetrating Matrigel-coated filters were counted after staining with Diff Quick. Representative images of TS cells from the following conditions are shown: **F)** exposure to ambient oxygen, **G)** exposure to low oxygen. Arrowheads show the location of cells penetrating through the Matrigel. **H)** Quantification of TS cell invasion. All experiments were performed in triplicate. Asterisks indicate significant differences among groups ($P < 0.05$; analysis of variance with Tukey's Test for comparisons).

2010) and trophoblast lineage-specific transcripts were evaluated. *Ankrd37*, *Egln1*, and *Bhlhe40* transcript concentrations were increased in response to low oxygen (**Fig. 2.18C**), as was *Tpbpa*, a transcript expressed by junctional zone precursors and some of their derivatives (**Fig. 2.18D**). In contrast, concentrations of *Prl3d1* transcripts, a trophoblast giant cell-specific transcript, and *Tfeb*, a labyrinthine trophoblast-specific transcript, were significantly decreased (**Fig. 2.18D**). All low oxygen-sensitive cellular measures were dependent upon HIF1B except for the *Tfeb* response (**Fig. 2.18C and D**). Hypoxia-mediated inhibition of gene expression is more frequently associated with HIF-independence (Semenza, 2010). Concentrations of other trophoblast-associated transcripts (*Gjb3*, *Prl5a1*, *Prl7b1*) were not reproducibly affected by low oxygen. The number of TS cells expressing TPBPA protein was increased by exposure to low oxygen and reversed by knockdown of HIF1B (Fig. 1.18E). Similar results were observed with a second independent *Hif1b* shRNA (**Fig. 2.19**). Mouse TS cells exposed to low oxygen also show an upregulation of *Tpbpa* gene expression (Adelman et al., 2000; Cowden Dahl et al., 2005; Zhang et al., 2011).

Oxygen tension also promoted the invasive phenotype of TS cells. Expression of mRNA for proteins implicated in trophoblast invasion and trophoblast-directed spiral artery remodeling (*Cdh1*, *Mmp9*, and *Mmp12*; Harris et al., 2010; Librach et al., 1991; Peters et al., 1999; Vicovac and Aplin, 1996) and trophoblast movement through Matrigel were evaluated. *Cdh1* transcript levels were decreased in response to low oxygen (**Fig. 2.20F**), while *Mmp9* and *Mmp12* transcript levels were stimulated by low oxygen. Low oxygen stimulated trophoblast invasion through Matrigel (**Fig. 2.20G**). Each of these TS cell responses to low oxygen was dependent on HIF1B (**Fig. 2.20F and G**).

Fig. 2.17. Oxygen tension, HIF1B signaling, and trophoblast cell lineage decisions.

TS cells maintained in stem cell conditions were exposed to low oxygen (0.5%) for 24 h in the presence of Control (Cntrl) shRNA or *Hif1b* shRNA-1. **A)** qRT-PCR analysis for *Hif1b* in TS cells exposed to ambient or low oxygen and control shRNA or *Hif1b* shRNA-1. **B)** Western blot analysis for TS cells exposed to ambient or low oxygen and control shRNA or *Hif1b* shRNA-1. **C)** qRT-PCR analyses for known hypoxia responsive genes (*Ankrd37*, *Egln1*, and *Bhlhe40*) TS cells exposed to ambient or low oxygen and control shRNA or *Hif1b* shRNA-1. All experiments were performed in triplicate. Asterisks indicate significant differences among groups ($P < 0.01$ for *Ankrd37* and *Egln1*, $P < 0.05$ for *Bhlhe40*; analysis of variance with Tukey's Test for comparisons). **D)** qRT-PCR analyses for trophoblast cell lineage markers (*Tpbpa*, *Prl3d1*, and *Tfeb*) in TS cells exposed to ambient or low oxygen and control shRNA or *Hif1b* shRNA-1. **A, C, and D)** qRT-PCR measurements (SYBR Green) were performed using the $\Delta\Delta CT$ method). 18S rRNA served as an internal control. All experiments were performed in triplicate. Asterisks indicate significant differences among groups ($P < 0.01$ for each gene; analysis of variance with Tukey's Test for comparisons). **E-G)** Immunofluorescence staining for TPBPA in TS cells exposed to ambient or low oxygen and control shRNA or *Hif1b* shRNA-1.

Fig 2.18 Examination of the effects of *Hif1b* shRNA-2 on TS cell responses to low oxygen.

TS cells maintained in stem cell conditions were exposed to low oxygen (0.5%) for 24 h in the presence of Control (Cntrl) shRNA or *Hif1b* shRNA-2. **A)** qRT-PCR analysis for *Hif1b* in TS cells exposed to ambient or low oxygen and control shRNA or *Hif1b* shRNA-2. **B)** Western blot analysis for TS cells exposed to ambient or low oxygen and control shRNA or *Hif1b* shRNA-2. **C).** qRT-PCR analyses for *Ankrd37*, a known hypoxia responsive gene. **D)** qRTPCR analysis for *Tpbpa*, a junctional zone lineage marker, in TS cells exposed to ambient or low oxygen and control shRNA or *Hif1b* shRNA-2. **A, C, and D)** qRTPCR measurements (SYBR Green) were performed using the $\Delta\Delta CT$ method). 18S rRNA served as an internal control. Asterisks indicate significant differences among groups (*Hif1b* transcript measurements: * $P < 0.05$, control shRNA vs *Hif1b* shRNA-2 in ambient conditions; ** $P < 0.01$, control shRNA vs *Hif1b* shRNA in low oxygen conditions; *Ankrd37* and *Tpbpa* transcript measurements: control shRNA vs *Hif1b* shRNA-2, * $P < 0.05$). All experiments were performed in triplicate. Analysis of variance and the Holm-Sidak method for multiple comparisons were used for all data analyses.

Fig. 2.19. Oxygen tension, HIF1B signaling, and trophoblast cell invasion. TS cells maintained in stem cell conditions were exposed to low oxygen (0.5%) for 24 h in the presence of Control (Cntrl) or *Hif1b* shRNA-1. **A)** qRT-PCR analyses for known hypoxia responsive genes (*Cdh1*, *Mmp9*, *Mmp12*) in TS cells exposed to ambient or low oxygen and control shRNA or *Hif1b* shRNA-1. qRT-PCR measurements (SYBR Green) were performed using the $\Delta\Delta CT$ method). 18S rRNA served as an internal control. All experiments were performed in triplicate. Asterisks indicate significant differences among groups ($P < 0.05$ for each gene; analysis of variance with Tukey's Test). **B-D)** Assessment of the effects of oxygen tension and HIF1B signaling on TS cell invasion. Cells penetrating Matrigel-coated filters were counted after staining with Diff Quick. Representative images of TS cells from the following conditions are shown: **B)** control shRNA and exposure to ambient oxygen, **C)** control shRNA and exposure to low oxygen, and **D)** *Hif1b* shRNA-1 and exposure to low oxygen. Arrows in **B** and **D** show the locations of invaded cells. **E)** Quantification of TS cell invasion. All experiments were performed in triplicate. Asterisks indicate significant differences among groups ($P < 0.05$; analysis of variance with Tukey's Test for comparisons). **F)** Schematic representation of the effects of NK cells on uterine spiral artery development, oxygen delivery to trophoblast stem cells, and HIF-dependent trophoblast differentiation.

Collectively, the results indicate that trophoblast lineage decisions are sensitive to oxygen tension. Hypoxia exposed TS cells are directed to differentiate towards a unique invasive and non-giant cell and non-labyrinthine trophoblast phenotype. This process is regulated by HIF1B.

DISCUSSION

The accumulation of NK cells in the uterus during pregnancy is a well-conserved biological event (Zhang et al., 2011). In this report, we investigated the role of uterine NK cells in the rat, a species with hemochorial placentation and deep intrauterine trophoblast invasion (Ain et al., 2003a). Our research demonstrates that NK cells act as regulators of hemochorial placentation. NK cells influence the development of uterine spiral arteries, at least in part, through their production of proangiogenic factors, such as VEGFs. Uterine spiral arteries deliver nutrients including oxygen to the developing placenta. Oxygen tension at the placentation site influences adaptive responses, which include trophoblast lineage decisions. Depending upon the internal milieu, trophoblast cells are differentially allocated to the uteroplacental vascular bed versus the placental–fetal interface, resulting in the creation of placentas with specialized properties for acclimation to specific environmental challenges. These experimental findings provide an important physiological link between the work of Croy and her colleagues demonstrating a role for NK cells in uterine spiral artery remodeling (Guimond et al., 1997; Zhang et al., 2011) and the efforts of Simon and coworkers elucidating the involvement of HIF signaling in the regulation of placentation (Adelman et al., 2000; Fryer and Simon, 2006).

There are temporal and quantitative features associated with the activities of NK cells and invasive trophoblast cells in uterine spiral artery maturation. NK cells promote uterine spiral artery growth toward the ectoplacental cone, a key event in the establishment of the hemochorial

placenta, and cause at least a partial disruption of spiral artery tunica media integrity. All NK cells are not the same and differentially contribute to the establishment of the maternal–fetal interface (Madeja et al., 2011). In the absence of NK cells, spiral artery extension is delayed and the tunica media initially remains intact. These observations are consistent with an angiogenic/vascular remodeling role for NK cells. The actions of NK cells on uterine spiral artery and stromal cell compartments are not a prerequisite for endovascular trophoblast invasion. This process is actually accelerated and more robust in the absence of NK cells. Although NK cell and invasive trophoblast cell populations are each sufficient to facilitate establishment of the hemochorial placenta, there are quantitative differences in the extent of spiral artery remodeling achieved by each cell population. NK cell actions on spiral arteries can be viewed as modest, especially in comparison with the substantial actions of endovascular invasive trophoblast cells on uterine spiral artery structure and nutrient delivery to the placenta. The latter actions are exaggerated in the absence of NK cells. By promoting spiral artery development, oxygen delivery, and establishing the hemochorial placenta, NK cells effectively delay endovascular trophoblast invasion. Delaying trophoblast entry into spiral arteries and the concomitant enhanced flow of maternal resources to the placenta is protective to the mother and can be viewed as a maternal adaptive strategy.

How do NK cells communicate with the developing placenta? Previous *in vitro* experimentation indicated that NK cells produce factors that directly affect the behavior of trophoblast cells, including the invasive trophoblast lineage (Hanna et al., 2006; Lash et al., 2010; Zhang et al., 2011). Some reports suggested that NK cell secretory products stimulate trophoblast invasion, whereas others concluded the opposite action. Differences in the findings are probably related to methodological issues, such as the origin of NK cell and trophoblast cell

preparations used in the analyses and/or other procedural considerations; however, they belie the most relevant mode of communication between NK cells and trophoblast cells, which is the delivery of oxygen. This view is supported by the similar placentation responses observed with two distinct *in vivo* manipulations: (i) NK cell depletion and (ii) maternal hypoxia (Rosario et al., 2008). Our results indicate that the direct actions of NK cells on trophoblast cells are of secondary consideration to the fundamental role of NK cells in the development of the vasculature and oxygen delivery.

Oxygen tension is a regulator of trophoblast cell function (Burton, 2009; Fryer and Simon, 2006; Genbacev et al., 1996; Zhou et al., 2011). A number of reports have demonstrated that trophoblast cells respond to oxygen restriction (Tuuli et al., 2011). *In vitro* experimentation has yielded a range of responses, some of which are contradictory, but, again, methodological differences are the likely cause for the discrepancies. Our *in vivo* findings led us to a critical window during placental morphogenesis (E8.5–E9.5 in the rat) that is especially sensitive to oxygen tension (Rosario et al., 2008). This is an interval where critical trophoblast lineage decisions are being finalized. These decisions impact morphogenesis of the placenta. Low oxygen favors TS cell and/or trophoblast precursor cell allocation to the junctional zone, a structure that establishes the placental interface with the uterus, including maternal vascular connectivity. Placentation sites are constructed to meet proximal challenges presented during the critical phase of their development, with the expectation that these challenges will continue throughout pregnancy and into postnatal extrauterine life. Problems and potentially disease arise when adaptations are ineffective and/or mismatches occur with the original environmental challenge directing placentation and subsequent prenatal and postnatal exposures. These

postulates are consistent with central roles for the placenta in fetal programming and the development of adult health and disease (Myatt, 2006).

In vivo placental adaptive responses can be simulated *in vitro* and include oxygen-sensitive lineage decisions. TS cell lineage responses are dependent upon HIF1B signaling pathways. HIF1B can interact with oxygen-sensitive HIF1A or HIF2A subunits or alternatively with other members of the bHLH-PAS family (Semenza, 2010). The HIF1A–HIF1B heterodimer is a transcription factor complex controlling expression of genes that are vital to cell survival under conditions of oxygen deprivation (Semenza, 2010). HIF1B binding partners and transcriptional targets in TS cells are unknown. Presumably, HIF1B is participating in transcriptional regulation of genes required for metabolic adaptations and also those controlling lineage decisions. The latter are keys to understanding how the invasive trophoblast cell lineage develops and potentially gaining insights about disorders that adversely affect placentation. In conclusion, hypoxia-activated trophoblast invasion/uterine spiral artery remodeling is an adaptive response regulated by NK cells that ensures appropriate placentation and protects pregnancy.

CHAPTER 3:

EPIGENETIC INVOLVEMENT OF THE HISTONE H3K9 DEMETHYLASE KDM3A

IN TROPHOBLAST STEM CELL ADAPTATIONS TO HYPOXIA

ABSTRACT

Delivery of oxygen is a key signal influencing both trophoblast cell differentiation and organization of the placentation site. Hypoxia promotes development of the invasive trophoblast lineage. In this study, we evaluated the impact of hypoxia on trophoblast stem (TS) cell differentiation. Initially, DNA microarray analyses were performed in rat TS cells exposed to ambient or low oxygen (0.5%). Hypoxia stimulated an upregulation of genes characteristic of an invasive/vascular remodeling phenotype, including matrix metalloproteinases (*Mmp9*, *Mmp12*) and a histone H3K9 demethylase (*Kdm3a*) transcript levels and a marked downregulation of stem state-associated genes, including E-cadherin (*Cdh1*). These responses were dependent upon hypoxia inducible factor (HIF) signaling. Hypoxia also induced global changes in trophoblast cell histone H3K9 methylation marks. A subset of the HIF targets was further shown to be KDM3A targets. Knockdown of KDM3A in rat TS cells inhibited *Mmp12* gene expression and disrupted histone H3K9 methylation status at the *Mmp12* locus. Conversely, ectopic expression of KDM3A in rat TS cells upregulated *Mmp12* expression in ambient conditions. KDM3A knockdown also decreased hypoxia-induced blastocyst outgrowth and reduced invasion through Matrigel-coated transwell chambers. In summary, hypoxia/HIF-directed epigenetic remodeling contributes to the control of TS cell adaptations, modulating trophoblast cell lineage development.

INTRODUCTION

Vascular remodeling is an important pregnancy associated adaptation in hemochorial placentation wherein the specialized trophoblast cell population called the invasive trophoblast lineage or alternatively extravillous trophoblast invade into the maternal spiral arterioles turning them into flaccid low resistance vessels (Georgiades et al., 2002; Red-Horse et al., 2004). Failure of trophoblast invasion and vascular remodeling is associated with pathological conditions like preeclampsia and intrauterine growth restriction (Kaufmann et al., 2003; Pijnenborg et al., 2006). The invasive trophoblast lineage arises from the trophoblast stem (TS) cells. The regulation of the differentiation program for this cell lineage is not well understood. Invasive trophoblast cells can be classified based on their route of invasion. In the rat, an initial wave of invasion consists of the endovascular invasive cell lineage, which moves within the spiral arteries, removes endothelium and often acquires a vascular endothelial phenotype known as pseudovasculogenesis (Harris, 2010; Harris et al., 2010; Pijnenborg et al., 1981b; Pijnenborg et al., 2006; Wiemers et al., 2003; Zhou et al., 1997). A second wave consists of the interstitial invasive cell lineage, which moves into the decidua and is situated between the uterine spiral arteries (Ain et al., 2003a; Pijnenborg et al., 1981a).

Oxygen tension is an important cue for placental development. During early gestation, oxygen tension at the placentation sites is low and then progressively increases with the establishment of functional placental compartments and vascular remodeling (Burton, 2009; Fryer and Simon, 2006; Genbacev et al., 1997; Rodesch et al., 1992). Cellular responses to low oxygen signaling are mediated by hypoxia inducible factor (HIF) transcription factors (Semenza, 2010). HIF transcription factors consist of heterodimer composed of oxygen sensitive HIF1A or

HIF2A and a constitutively active HIF1B (also known as aryl hydrocarbon receptor nuclear translocator, ARNT).

Under oxygen replete conditions HIF proteins are hydroxylated by prolyl hydroxylases and targeted for degradation by the ubiquitin ligase Von Hippel Lindau protein (Ivan et al., 2001; Jaakkola et al., 2001b). Under low oxygen tensions, HIF proteins are stabilized, dimerize with HIF1B, and bind hypoxia response elements (Wang et al., 1995). HIF1A and HIF2A are known to have unique as well as overlapping targets (Bracken et al., 2006; Hu et al., 2006a; Raval et al., 2005). Mutagenesis of genes encoding components of the HIF pathway including the *Hif1a*, *Hif2a*, *Hif1b*, prolyl hydroxylase domain protein 2 (*Phd2*; also known as *Egln1*), and Von Hippel-Lindau (*Vhl*) genes, are associated with failures in placentation (Adelman et al., 2000; Fryer and Simon, 2006). Hypoxia exposure can redirect placental organization and promote development of the invasive trophoblast cell lineage (Chakraborty et al., 2011; Rosario et al., 2008).

Cellular adaptations to hypoxia include epigenetic reorganization. Hypoxia leads to a range of histone modifications at target genes (Johnson et al., 2008; Melvin and Rocha, 2012) and specifically regulates a number of JmJc domain containing histone demethylases (Beyer et al., 2008; Krieg et al., 2010; Pollard et al., 2008; Wellmann et al., 2008). KDM3A (also known as JMJD1A) is a hypoxia responsive JmJc containing histone H3K9 demethylase, specifically acting on histone H3K9 monomethyl and dimethyl substrates (Yamane et al., 2006). KDM3A is implicated in the regulation of cell differentiation (Herzog et al., 2012; Lockman et al., 2007), maintenance of embryonic stem cell stem state (Ko et al., 2006; Loh et al., 2007), in cancer cell invasion (Guo et al., 2011; Yamada et al., 2012; Yamane et al., 2006) as well as *in vivo* tumor cell growth (Krieg et al., 2010). Targeted *in vivo* *Kdm3a* mutagenesis in mice is associated with

failures in male germ cell development and metabolic syndrome (Liu et al., 2010; Okada et al., 2007; Tateishi et al., 2009).

In this chapter, we examine the actions of hypoxia signaling on development of the invasive trophoblast cell lineage. Hypoxia-responsive gene expression in TS cells is elucidated and the contributions of HIF and KDM3A to hypoxia-dependent changes in TS cell biology were determined. Hypoxia exposure upregulates a signature set of genes involved in cellular movement and invasion. HIF regulated KDM3A appears to be at the center of global and genespecific epigenetic changes. In summary, HIF-directed epigenetic remodeling contributes to the control of TS cell adaptations to low oxygen and development of the invasive trophoblast cell lineage.

MATERIALS AND METHODS

Animals and tissue collection

HSD rats were acquired from Harlan Laboratories (Indianapolis, IN). Animals were housed in an environmentally controlled facility with lights on from 0600-2000 h and allowed free access to food and water. Virgin female rats 8-10 weeks of age were cohabited with adult males (>3 months of age) of the same strain. Mating was assessed by inspection of vaginal lavages. The presence of sperm in the vaginal lavage was considered gestation day (E)0.5. Rat embryos were collected by flushing uteri with M2 medium (Millipore, Temecula, CA) at E4.5.

Pregnant rats were placed in a hypoxic (8.5% oxygen) gas-regulated chamber (BioSpherix, Lacona, NY) from E8.5 to E9.5. Pair-fed and ad libitum-fed pregnant rats exposed to ambient conditions (normoxia) served as controls. Rat placental tissues were collected on E9.5. The E9.5 primordial placental structure is referred to as the ectoplacental cone. Placentation site

dissections were performed as previously described (Ain et al., 2006). Tissues for histological analysis were frozen in dry-ice cooled heptane and stored at -80°C. Tissue samples for protein or RNA extraction were frozen in liquid nitrogen and stored at -80°C until processed. The University of Kansas Animal Care and Use Committee approved protocols for the care and use of animals.

Rat TS cell culture

Blastocyst-derived rat TS cells (Asanoma et al., 2012) were used to evaluate the effects of low oxygen on trophoblast lineage decisions. TS cells were cultured in Basal Culture Medium [RPMI 1640 (Cellgro, Herndon, VA), 20% fetal bovine serum (FBS; Atlanta Biologicals, Norcross, GA), 100 µM 2-mercaptoethanol (Sigma-Aldrich, St. Louis, MO), 1 mM sodium pyruvate (Cellgro), 50 µM penicillin and 50 U/ml streptomycin (Cellgro)] supplemented with 70% rat embryonic fibroblast (REF) conditioned medium, FGF4 (25 ng/ml; Sigma-Aldrich) and heparin (1 µg/ml; Sigma-Aldrich). TS cells maintained in the stem cell/proliferative state were exposed to a range of oxygen tensions (0.5 to 2%) and 5% CO₂ using a NAPCO Series 8000WJ incubator (Thermo Scientific, Pittsburgh, PA) for 24 h and then harvested for cell and molecular analyses.

Immunocytochemistry

Immunocytochemical analyses were performed on 10 µm frozen tissue sections using indirect immunofluorescence detection using goat anti-mouse IgG tagged with Alexa 488 (Invitrogen, Carlsbad, CA, Cat. No. A11029; 1:1000 dilution), goat anti-mouse IgG tagged with Alexa 568 (Invitrogen, Cat. No. A11031; 1:400 dilution), or goat anti-rabbit IgG tagged with cyanine 3 (Cy3; Jackson ImmunoResearch Laboratories, West Grove, PA, Cat. No. 111-165-

003; 1:250 dilution). Nuclei were visualized with 4',6-diamidino-2-phenylindole (DAPI, Molecular Probes, Carlsbad, CA). Negative controls were performed with normal rabbit serum or isotype-specific control mouse IgG and did not exhibit positive reactivity in the tissue sections. Processed tissue sections were inspected and images recorded with a Leica MZFLIII stereomicroscope equipped with a charge-coupled device (CCD) camera (Leica, Welzlar, Germany).

Western blot analysis

KDM3A, ACTB, histone H3, and histone H3K9 methylation modifications (monomethylated: H3K9me1, dimethylated: H3K9me2, trimethylated: H3K9me3) were monitored by western blot analysis. Rat TS cell lysates were prepared in radioimmunoprecipitation assay (RIPA) buffer (10 mM Tris-HCl, pH 7.2, 1% Triton X-100 or 1% Nonidet P-40, 1% sodium deoxycholate, 0.1% SDS, 150 mM NaCl, 5 mM EDTA, 1 mM sodium orthovanadate, 1 mM phenylmethylsulfonyl fluoride, 10 µg/ml aprotinin). Protein concentrations were determined by the DC protein assay (Bio-Rad, Hercules, CA). Proteins were separated by SDS-PAGE and transferred onto nitrocellulose membranes. Immunoreactive proteins were detected with rabbit antibodies to KDM3A (Sigma-Aldrich, Catalog No. SAB3500093) and ACTB (Sigma-Aldrich, Catalog No. A1978). Antibodies to histone H3 and histone H3K9 methylated isoforms were obtained from (Abcam, Cambridge, MA; histone H3, Catalog No. ab1791; H3K9me1, Catalog No.ab9045; H3K9me2, Catalog No. ab1220; H3K9me3, Catalog No.ab8898). Immunoreactive proteins were visualized by enhanced chemiluminescence according to the manufacturer's instructions (Amersham Biosciences, Piscataway, NJ).

DNA microarray

Affymetrix 230 2.0 DNA microarray chips (Affymetrix, Santa Clara, CA) were probed with cDNAs generated from rat trophoblast stem cells grown under oxygen replete conditions or low (0.5%) oxygen exposure. Each treatment group was repeated in triplicate. RNA samples were hybridized to the Affymetrix 230 2.0 DNA microarray chip using the GeneChip® Hybridization Oven 640 (Affymetrix). Washing and staining of hybridized chips were conducted using the GeneChip® Fluidics Station 450 (Affymetrix). Chips were scanned using the Affymetrix GeneChip® Scanner 3000 (Affymetrix) with autoloader by the KUMC Biotechnology Support Facility. Hybridization signals were normalized with internal controls using the Mas5 algorithm in Expression Console (Affymetrix) and fold change computed. Significant differences were determined by paired two-tailed Student t-tests. Microarray data was processed for functional analysis using Ingenuity Pathway Analysis (Redwood City, CA). Probe sets included in the analysis were restricted to those changing at least 1.5 fold between group comparisons with signal strengths of ≥ 500 for the maximal value.

Quantitative RT-PCR (qRT-PCR)

Total RNA was extracted from cells and tissues using TRIzol reagent (Invitrogen). cDNAs were synthesized from total RNA (1 μ g) for each sample using Superscript 2 reverse transcriptase (Invitrogen), diluted five times with water, and subjected to qRT-PCR to estimate mRNA levels. Primers were designed using Beacon primer designer (Applied Biosystems, Foster City, CA). Primer sequences can be found in **Table 3.1.1** and **3.1.2**. Real-time PCR amplification of cDNAs was carried out in a reaction mixture (20 μ l) containing SYBR GREEN PCR Master Mix (Applied Biosystems,) and primers (250 nM each). Amplification and fluorescence detection were carried out using the ABI Prism 7500 real time PCR system

(Applied Biosystems). Cycling conditions included an initial hold step (95 °C for 10 min) and 40 cycles of a two-step PCR (92 °C for 15 sec, then 60 °C for 1 min), followed by a dissociation step (95 °C for 15 sec, 60 °C for 15 sec, and then 95 °C for 15 sec). The comparative cycle threshold method was used for relative quantification of the amount of mRNA for each sample normalized to 18S RNA.

Chromatin immunoprecipitation (ChIP)

ChIP analysis was performed according to a previously published procedure (Krieg et al. 2010). Briefly, TS cells were grown in 150-mm dishes for two days in ambient conditions and then exposed to 0.5% oxygen for 24 hours. Cells were then fixed with 1% formaldehyde, and purified nuclear lysates were sonicated using a Diagenode Bioruptor (Diagenode, Denville, NJ) to prepare DNA fragments at a size of approximately 500 bp. Lysates were immunoprecipitated with 3µg of appropriate antibody (H3K9me1, Catalog No.ab9045; H3K9me2, Catalog No. ab1220, ABCAM) or with rabbit or mouse IgG (BD Biosciences). Immunoprecipitated chromatin fragments were eluted from agarose beads. DNA-protein interactions were reverse cross-linked and purified using a QiaQuick PCR purification kit (Qiagen). Purified DNA fragments were assessed by quantitative PCR (qPCR) using *Mmp12* promoter-specific primers (**Table 3.1**) and SYBRgreen PCR master mix (Applied Biosystems). Specific primers were used for qPCR measurements of H3K9me1 and H3K9me2 enrichment site A (–459 to –322) occupancy (forward, AAGGATTCGTGTATTCTAGCA; reverse, ACGCCATTAGCAGAGTTT; 138-bp product) and site B (–207 to –10) occupancy (forward, TGAGTGATGACTTAGACAATG; reverse, TCCTTTCAGCAACAGAGT; 197-bp product) at *Mmp12* locus. Relative occupancy/enrichment was normalized to input samples by use of the $\Delta\Delta CT$ method.

Short hairpin RNA (shRNA) constructs and production of lentivirus

Hif1b shRNA constructs cloned into the pLKO.1 vector were obtained from Open Biosystems (Huntsville, AL). Several shRNAs were tested for each gene evaluated. The *Hif1b* shRNA sequences used in this analysis are as follows: i) *Hif1b* shRNA-1:

5'GAGAAGTCAGAAGGTCTCTTTTCTCGAGTAAAGAGACCTTCTGACTTCTC3'; ii)

Hif1b shRNA-2:

5'CCAGACAAGCTAACCATCTTACTCGAGTAAGATGGTTAGCTTGTCTGG3'. The

Kdm3a shRNA sequences used in the analysis are as follows: i) *Kdm3a* shRNA-1:

5'CCGGTGCGGGTAGAAGGCTTCTTAACTCGAGTTAAGAAGCCTTCTACCCGCATTTT TG3'; ii) *Kdm3a* shRNA-2:

5'CCGGGAAGTTCCTGAGCAAGTTATTCTCGAGAATAACTTGCTCAGGAAGTTCTTTT TG3'.

The control shRNA, which targets no known mammalian gene, pLKO.1-shSCR (Plasmid 1864), was obtained from Addgene (Cambridge, MA) and has the following sequence

5'CCTAAGGTAAAGTCGCCCTCGCTCTAGCGAGGGCGACTTAACCTTAGG3' (Sarbasov et al., 2005a). Third generation lentiviral packaging vectors were purchased from Addgene and included: pMDLg/pRRE (Plasmid 12251), pRSV-Rev (Plasmid 12253) and pMD2.G (Plasmid 12259). Lentiviral particles were produced as previously reported (Lee et al., 2009). In brief, 293FT cells (Invitrogen) were transiently transfected using Lipofectamine 2000 (Invitrogen) with the following plasmids: shRNA containing transducing vector, third-generation packaging system plasmids (pMDLg/pRRE and pRSV-Rev; 104), and a VSVG envelope plasmid (pMD2.G). After transfection, cells were maintained in 50% DMEM with high glucose (Cellgro), 45% Opti-MEM I (Invitrogen) and 5% FBS. Culture supernatants containing lentiviral

particles were harvested every 24 h for two to three days. Supernatants were centrifuged to remove cell debris, filter sterilized, concentrated by ultracentrifugation, and stored at -80°C until used.

Ectopic expression of Kdm3a

Full length mouse *Kdm3a* expression vector was kindly provided by Dr. Christopher Mack, University of North Carolina, Chapel Hill, NC. Flag-tagged pcDNA3 vector expressing *Kdm3a* was transfected into rat TS cells using Lipofectamine 2000 (Lifetechnologies, NY) transfection reagent according to manufacturer's instructions. Cells were selected with Geneticin (Lifetechnologies, NY) for 5 days before experiments.

Matrigel invasion assay

The invasive ability of rat TS cells was measured as previously described (Peters et al., 1999). Rat TS cells were placed in Matrigel invasion chambers (BD Biosciences) at a density of 2×10^4 cells per chamber. Cells were allowed to invade for 24 h. Membranes were collected and stained with Diff-Quick (Dade Behring, Newark, DE). Invading cells were visualized by light microscopy and counted.

Blastocyst outgrowth assay

The blastocyst outgrowth assay was performed as reported before (Armant et al., 1986). Blastocysts were obtained from d4.5 pregnant rats by flushing them from the uterine horns with 0.1 ml DMEM medium (Lifetechnology). The embryos were cultured at 37°C in a 5% CO₂ incubator for 48 hours to allow hatching from the zona pellucida. They were cultured in rat TS Basal Culture Medium. The attached blastocysts were exposed to 0.5 % oxygen for 24 hours in a NAPCO Series 8000WJ incubator (Thermo Scientific, Pittsburgh, PA) and then fixed in 4%

paraformaldehyde solution. The surface area of outgrowth was visualized using light microscopy and measured using Image J software.

Statistical analyses

Data analyses were performed using SigmaPlot 11.2 statistical software package (Systat Software, Inc, San Jose, CA). Specific details of the analyses are presented in the figure legends.

RESULTS

TS cell transcriptome responses to low oxygen

Hypoxia signaling regulates the development of the invasive trophoblast cell lineage (Chakraborty et al., 2011; Rosario et al., 2008), which can be effectively modeled *in vitro* using rat TS cells (Chakraborty et al., 2011). As a first step to identify potential regulatory mechanisms downstream of hypoxia exposure, we profiled the transcriptomes of TS cells exposed to ambient and 0.5% oxygen for 24 h using DNA microarray analysis (**Fig. 3.1A**). This culture condition activates HIF signaling pathways and promotes development of the invasive trophoblast cell lineage (Chakraborty et al., 2011). All DNA microarray data will be deposited in the Gene Expression Omnibus (GEO) repository. Appendix Tables **A 2.1** and **A 2.2** show abbreviated lists of hypoxia-regulated transcripts. Genes listed in these tables are those with arbitrary expression signal strengths of ≥ 500 , a fold change of ≥ 1.5 , and a P value ≤ 0.05 . Similar numbers of transcripts were significantly upregulated (n=786) or downregulated (n=838) by low oxygen exposure (**Fig. 3.1B**). We utilized Ingenuity Pathway Analysis software (Ingenuity Systems, Redwood City, CA) to evaluate signaling pathways affected by exposure to low oxygen. Functions associated with general cellular movement and survival were upregulated

Fig3.1. Analysis of microarray data. **A)** Schematic showing the experimental plan of hypoxia exposure of rat TS cells. **B)** Scatter graph showing the signal intensity probe sets.

following exposure to low oxygen exposure, whereas cell-to-cell association and stem cell maintenance pathways were downregulated (**Fig. 3.2**). A subset of differentially regulated transcripts was further analyzed and validated using qRT-PCR. The transcripts upregulated by low oxygen included transcripts encoding extracellular matrix remodeling enzymes (*Mmp12*, *Mmp9*, *Plau*, *Dpp3*), a histone demethylase (*Kdm3a*), key regulators of glycogen and glucose metabolism (*Ppp1r3c*), and a number of transcripts known to be regulated by hypoxia and the HIF signaling pathway (Benita et al., 2009; Semenza, 2010) (**Table 3.2.1**). In contrast, the downregulated group included cell-cell adhesion (*Cdh1*), TS cell-associated (*Cdx2*, *Bmp4*, *Id2*, *Satb1*), cell proliferation-associated (*Rbm3*, *Lin28*), and trophoblast giant cell-associated (*Hand1*) transcripts (**Table 3.2.2**). In summary gene expression analysis is consistent with rat TS cells adapting to low oxygen by differentiation into an invasive trophoblast cell lineage.

HIF dependence of TS cell responses to low oxygen

Many cellular adaptations to hypoxia are mediated by the HIF signaling pathway (Semenza, 2010). Since hypoxia-activated TS cell differentiation towards an invasive trophoblast cell lineage is dependent on HIF signaling (Chakraborty et al., 2011), we next focused on identification of hypoxia-responsive TS cell transcripts, which were dependent on HIF signaling. In order to determine the involvement of the HIF signaling pathway in the regulation of TS cell adaptations to low oxygen, HIF1B (the common transcriptional partner for HIF1A and HIF2A) was silenced using lentiviral transduction of HIF1B-specific shRNAs (Chakraborty et al., 2011). Knockdown of HIF1B attenuated the hypoxia-dependent upregulation of several transcripts, such as: *Mmp12*, *Mmp9*, *Kdm3a*, *Ppp1r3c*, *Il33* and *Bhlhe40* (**Fig. 3.3 A**). In contrast, the HIF dependence of TS cell transcripts downregulated by low oxygen was not as

uniform. *Cdh1*, *Hand1* and *Rbm3* transcript decreases in response to hypoxia were dependent upon HIF signaling but other transcripts like *Id1*, *Lin28*, and *Satb1* which downregulated in response to low oxygen were not significantly affected by HIF1B knockdown (**Fig. 3.3 B**). Similar patterns of HIF-dependence of hypoxia upregulated versus downregulated genes have been described (Semenza, 2010). The results demonstrate that HIF controls oxygen tension-sensitive genes potentially involved in regulating development of the invasive trophoblast cell lineage.

Role of KDM3A in TS cell adaptations to low oxygen

Among the candidate mediators of HIF action on trophoblast development identified by transcriptome profiling (see above), the discovery of KDM3A was compelling. *Kdm3a* is a known hypoxia responsive gene and is a direct target of HIF action (Beyer et al., 2008; Krieg et al., 2010; Pollard et al., 2008; Wellmann et al., 2008; Yang et al., 2009). Additionally, histone H3K9 demethylases, including KDM3A, are known regulators of differentiation of a range of cell lineages, such as embryonic stem cells, extraembryonic endoderm, neural crest, neuronal cells, mammary epithelium, and muscle (Kawazu et al., 2011; Ko et al., 2006; Lockman et al., 2007; Loh et al., 2007; Nottke et al., 2009; Pedersen and Helin, 2010; Qi et al., 2010; Strobl-Mazzulla et al., 2010; Verrier et al., 2011; Wen et al., 2009).

Hypoxia and trophoblast differentiation modulate KDM3A expression. Initially, we examined KDM3A mRNA and protein responses to hypoxia using *in vitro* and *in vivo* models. Exposure of rat TS cells to 0.5% oxygen was an effective stimulus to increase KDM3A transcript and protein levels (**Fig. 3.4 A,B &C**). KDM3A protein peaked at 16 h following initiation of the exposure to low oxygen. Two related histone H3K9 demethylases, *Kdm3b* and *Kdm3c*, were not

Fig. 3.4. KDM3A is upregulated on hypoxia exposure . TS cells maintained in stem cell conditions were exposed to low oxygen (0.5%) for 24 h. **A)** qRT-PCR analyses for *Kdm3a* in TS cells exposed to ambient or low oxygen. qRT-PCR measurements (SYBR Green) were performed using the $\Delta\Delta CT$ method). 18S rRNA served as an internal control. Asterisks indicate significant differences among groups ($P < 0.05$ for each gene; Student's tTest). All experiments were performed in triplicate. **B)** Western blot analysis of KDM3A on rat TS cell exposed to ambient or low oxygen (collected every four hour interval upto 24 hours) conditions. **C)** Immunofluorescence staining for KDM3A in TS cells exposed to ambient or low oxygen. **D)** qRT-PCR analyses for *Kdm3b* and *Kdm3c* in TS cells exposed to ambient or low oxygen.

upregulated following rat TS cell exposure to low oxygen (**Fig. 3.4D**). KDM3A transcript and protein levels were also upregulated in the ectoplacental cone following exposure of E8.5 pregnant rats to hypoxic conditions for 24 h (**Fig. 3.5**). These *in vivo* conditions were also associated with increases in the expression of other hypoxia responsive genes, including *Mmp12* and *Ppp1r3c* (**Fig. 3.6**). Increased KDM3A expression also accompanies *in vitro* trophoblast differentiation induced by mitogen withdrawal and *in vivo* trophoblast development (**Fig. 3.7 A, B, C, D and E**). We utilized BeWo trophoblast cells as a human trophoblast cell model. BeWo trophoblast cells also respond to hypoxic conditions with increased KDM3A expression (**Fig. 3.8. A&B**). KDM3A could be localized on human placentation sites (**Fig. 3.8. C**) prominently in the first trimester extra villous trophoblast (EVT) columns. A marked decrease in expression of KDM3A is observed at term placentation sites. The cytokeratin positive interstitial trophoblast cells continue to express KDM3A at term. Collectively, the results indicate that KDM3A expression is regulated by hypoxia and by developmental events leading to trophoblast cell specialization.

Identification of KDM3A responsive genes.

Since KDM3A exhibited a pronounced increase accompanying hypoxia exposure, we postulated that KDM3A might contribute to the regulation of a subset of the genes differentially regulated by exposure to low oxygen. We utilized shRNAs to disrupt KDM3A expression (**Fig. 3.9**). Knockdown of KDM3A interfered with TS cell gene expression responses to low oxygen (**Fig. 3.10**). The hypoxia responsiveness of *Mmp12*, *Ppp1r3c*, *Il33*, *Cd200*, *Plod2* and *LOC580835* like *Cullin 7* gene expression was attenuated by knockdown of KDM3A, whereas other hypoxia-responsive genes like *Bhlhe40*, *Plau*, *Dpp3*, *Ankrd37*, *Cdh1* and *Rbm3* were

Fig. 3.5. KDM3A is upregulated on hypoxia exposure *in vivo* . **A)** Rats were exposed to 8.5% oxygen for 24 h beginning on d8.5 and sacrificed on gestation d9.5. unaffected by KDM3A manipulation (**Fig. 3.10**). A complementary experiment was performed to examine the regulatory role of KDM3A on gene expression independent of hypoxia. Ectopic expression of KDM3A significantly upregulated *Mmp12* and *Ppp1r3c* gene expression in TS cells grown in ambient conditions; however, this treatment was ineffective in altering *Il33* transcript levels (**Fig 3.11**). Thus, KDM3A is an effective intermediary controlling the expression of a subset of TS cell genes regulated by hypoxia/HIF signaling. The dependence on KDM3A is not the same for all KDM3A responsive genes.

KDM3A regulates hypoxia-activated trophoblast cell invasion.

Hypoxia is an effective activator of invasive trophoblast lineage development (Chakraborty et al., 2011; Rosario et al., 2008). We next explored whether KDM3A was involved in development of the hypoxia-activated invasive trophoblast lineage. Two model systems were evaluated: i) TS cell invasion through Matrigel chambers; ii) blastocyst outgrowths (Ain et al., 2003b; Armant et al., 1986; Chakraborty et al., 2011; Peters et al., 1999). Exposure to low oxygen stimulates TS cell acquisition of an invasive phenotype and penetration through the extracellular matrix and the outward migration and spreading of trophoblast cells from attached blastocysts. KDM3A knockdown significantly decreased hypoxia-stimulated trophoblast invasion through Matrigel chambers and blastocyst outgrowth (**Fig. 3.12 A & B**). Ectopic expression of KDM3A in TS cells grown under ambient conditions significantly increased their movement through Matrigel chambers (**Fig. 3.12 C**). Collectively, these results indicate that KDM3A is a key regulator of TS cell adaptations to hypoxia, including gene expression and their acquisition of an invasive phenotype.

Hypoxia-dependent histone modifications at the *Mmp12* locus

Several genes upregulated in low oxygen exposed TS cells are sensitive to KDM3A manipulation, including, *Mmp12*. MMP12 is a matrix metalloelastase that has been implicated in trophoblast-directed uterine spiral artery remodeling (Harris, 2010). KDM3A is a lysine demethylase with specificity for histone H3K9me1 and H3K9me2 (Yamane et al., 2006). Consequently, we next examined histone H3K9 methylation status within the proximal *Mmp12* promoter region and its susceptibility to regulation by hypoxia using a ChIP assay. Under low oxygen tensions, there was significant loss of enrichment of H3K9 mono and dimethyl groups at the proximal promoter region of *Mmp12* (**Fig. 3.13**). Such a change in the methylation landscape of histone H3K9 at the *Mmp12* locus is consistent with hypoxia-induced KDM3A expression and its known lysine demethylase activity.

Hypoxia-dependent global TS cell histone H3K9 methylation modifications

In other cell types, it has been shown that hypoxia exposure can influence H3K9 methylation status (Chen et al., 2006; Johnson et al., 2008). Such observations prompted us to evaluate the effects of hypoxia on global H3K9 methylation in TS cells. Western blots for H3K9 methylation modifications were performed using lysates harvested from TS cells exposed to ambient or hypoxic (0.5% oxygen for 24 h) conditions. Low oxygen exposure was associated with prominent decreases in global H3K9me1 and H3K9me2, whereas modest changes were observed for H3K9me3 (**Fig. 3.14 A**). Immunocytochemistry in TS cell populations was consistent with a hypoxia-driven global down regulation of H3K9me1 (**Fig 3.14 C**). Disruption of KDM3A partly obviated the global effects of hypoxia on H3K9me1 (**Fig. 3.14 B**).

Fig 3.12. KDM3A regulates hypoxia activated trophoblast invasion. **A)** Assessment of the effects of oxygen tension and KDM3A expression on TS cell invasion. Cells penetrating Matrigel-coated filters were counted after staining with Diff Quick. Representative images of TS cells from the following conditions are shown: control shRNA and exposure to ambient oxygen, control shRNA and exposure to low oxygen, and *Kdm3a*shRNA-1 &2 and exposure to low oxygen. The bar graph shows quantification of TS cell invasion. All experiments were performed in triplicate. Asterisks indicate significant differences among groups ($P < 0.05$; analysis of variance with Tukey's Test for comparisons). **B)** Effects of oxygen tension and KDM3A expression on blastocyst outgrowth assay. The area of the outgrowth was measured using Image J software. Representative images of blastocyst outgrowths from the following conditions: control shRNA and exposure to ambient oxygen, control shRNA and exposure to low oxygen, and *Kdm3a*shRNA-1 &2 and exposure to low oxygen. The bar graph shows quantification of outgrowth area in mm^2 ($P < 0.05$; analysis of variance with Tukey's Test for comparisons).. **C)** Assessment of the effects of ectopic KDM3A expression on TS cell invasion. Cells penetrating Matrigel-coated filters were counted after staining with Diff Quick. Representative images of TS cells from the following conditions are shown: pcDNA3 and pcDNA3 expressing flag tagged *Kdma3a* in ambient oxygen tensions. The bar graph shows quantification of TS cell invasion. Asterisks indicate significant differences among groups ($P < 0.05$; Student's t Test).

Complementary experiments were performed on E9.5 placentation sites of control and hypoxia exposed (8.5% O₂ for 24 h) rats. The *in vivo* findings are consistent with hypoxia-driven global changes in H3K9 methylation, especially H3K9me1 (**Fig. 3.14 D& E**).

In summary, our findings indicate that hypoxia has a global impact on chromatin reorganization in TS cells leading to the development of the invasive trophoblast cell lineage and places KDM3A within regulatory pathways controlling these events.

DISCUSSION

During development, the hemochorial placenta is constructed in response to stimuli present in the maternal environment and optimized to facilitate nutrient delivery to the fetus. Plasticity in placental organization is achieved via differential regulation of TS cell proliferation and differentiation. Among the myriad of potential signals emanating from the maternal environment, oxygen delivery plays a significant role. Eukaryotic cells have evolved mechanisms for adapting to exposure to low oxygen (Semenza, 2010). TS cells utilize these conserved hypoxia-signaling pathways to control placentation (Adelman et al., 2000; Cowden Dahl et al., 2005; Maltepe et al., 2005; Xie et al., 2011; Zhou et al., 2011). The proximal response of TS cells to hypoxia is differentiation into invasive trophoblast capable of targeting uterine spiral arteries with the goal of expanding nutrient flow to the placenta and fetus (Chakraborty et al., 2011; Rosario et al., 2008).

TS cell adaptations to hypoxia are hierarchically regulated. Low oxygen exposure elicits a broad spectrum of changes in the TS cell transcriptome highlighted by activation of genes

Fig. 3.13. ChIP analysis at *Mmp12* locus.ChIP analysis of H3K9me1 and H3K9me2 enrichment at rat *Mmp12* proximal promoter region (-500 to +1 bp) on sites A and B (described in materials and methods section) in rat TS cells exposed to ambient O₂ or 0.5% O₂. IgG was included as a negative control. Values significantly different are indicated (*, P<0.05).

associated with cellular movement, invasion, and vascular remodeling. A subset of the hypoxia-induced changes in gene expression is dependent on HIF signaling, especially those genes activated by hypoxia. A subset of HIF-dependent genes is linked to the actions of KDM3A. Thus a path can be constructed from hypoxia to HIF activation to increases in KDM3A expression to alterations in the histone methylation status of genes promoting development of the invasive trophoblast lineage.

Hypoxia, HIF, and KDM3A have been implicated in regulating epithelial mesenchymal transition and cell invasion in disease states, including cancers (Guo et al., 2011; Krieg et al., 2010; Semenza, 2010; Yamada et al., 2012; Yamane et al., 2006; Yang et al., 2009). HIF binds to hypoxia response elements (HREs) at the *Kdm3a* locus and stimulates *Kdm3a* transcription (Krieg et al., 2010; Mimura et al., 2012). KDM3A targets histone H3K9me1 and H3K9me2 for demethylation and thus extending and amplifying HIF signaling (Krieg et al., 2010; Mimura et al., 2012). Histone H3K9me2 marks are associated with gene repression, and thus their removal is linked to gene activation (Li et al., 2007). Loss of the histone H3K9me2 and H3K9me1 modifications at the *Mmp12* locus correlate with increased *Mmp12* expression. MMP12 is a matrix metalloelastase expressed by invasive trophoblast and situated downstream of hypoxia, HIF, and KDM3A regulation, with actions on uterine spiral arteries facilitating nutrient delivery to extraembryonic and embryonic tissues (Harris, 2010).

KDM3A is specifically targeted to its sites of action within the genome. HIF1A can recruit KDM3A to some of its target genes, including the *Glut3* locus, resulting in H3K9me2 demethylation and transcriptional upregulation (Mimura et al., 2012). OCT1 is also linked to

Fig. 3.14. Effect of hypoxia signaling on global H3K9methylation status. A) Western blot analysis of rat TS cell exposed to ambient or 0.5% O₂ for H3K9me1, H3K9me2 and H3K9me3. B) Western blot analysis of TS cells under following conditions: Control shRNA and ambient O₂, Control shRNA and 0.5% O₂, *Kdm3a* shRNA1 or *Kdm3a* shRNA2 and ambient O₂, and *Kdm3a* shRNA-1 or *Kdm3a* shRNA-2 and 0.5% O₂ for H3K9me1, H3K9me2 and H3K9me3. E

KDM3A recruitment to target genes where KDM3A acts to remove repressive histone marks (Shakya et al., 2011). OCT1 has also been identified as a participant in the regulation of trophoblast lineage development (Sebastiano et al., 2010). KDM3A is also known to interact with nuclear receptors, including the androgen receptor, through an LXXLL motif (Yamane et al., 2006), providing a method of targeting to relevant loci. Although the androgen receptor does not appear to contribute to the regulation of trophoblast biology, other nuclear receptors such as PPAR γ and ESRRB have been linked to both trophoblast and hypoxia regulation (Ao et al., 2008; Parast et al., 2009; Rielland et al., 2008). In hypoxic TS cells, KDM3A may be delivered by HIF transcription factors to its gene targets in some instances, whereas arrival at other loci may be entirely independent of HIF (*Mmp12*, *Ppp1r3c*). This conclusion is based on the observed differential outcomes of *loss-of-function* and *gain-of-function* KDM3A manipulations in TS cells shown in this report. Elucidation of mechanisms controlling KDM3A arrival at its appropriate targets in the TS cell genome is an important future task.

Cells respond to hypoxia with global changes in histone modifications (Johnson et al., 2008; Melvin and Rocha, 2012). This epigenetic reorganization is postulated to establish a less compact chromatin environment, facilitating rapid transcriptional activation of genes and adaptations to hypoxic conditions. Consistent with such observations TS cells respond to hypoxia with global changes in histone H3K9me1 and H3K9me2. Recently H3K9me1 has achieved some prominence. Histone H3K9 methylation is a progressive event, wherein H3K9 monomethyl transferases deposit methyl groups on unmethylated histone H3K9 yielding H3K9me1 and H3K9me2 states. The H3K9 monomethylation mark serves as a recognition signal for SUV39H, an H3K9 methyl transferase, which can convert H3K9me1 to a more

repressive H3K9me3 and bring about heterochromatic silencing (Towbin et al., 2012). Changes in histone H3K9 methylation, particularly H3K9 monomethylation, are also observed during chromatin assembly implicating its role in maintaining chromatin architecture (Jasencakova and Groth, 2010; Loyola et al., 2009). H3K9 methylation status and SUV39H have also been linked to development of the trophoblast lineage (Alder et al., 2010; Rugg-Gunn et al., 2010).

A role for KDM3A under hypoxic conditions may seem contradictory based on its known enzymatic properties. KDM3A is a α ketoglutarate-dependent dioxygenase and requires oxygen for enzymatic activity (Chen et al., 2006; Johnson et al., 2008). Our findings are consistent with Beyer and coworkers who observed the preservation of KDM3A histone demethylase activity in cells exposed to 0.5% oxygen (Beyer et al., 2008). Another α ketoglutarate-dependent dioxygenase and known regulator of HIF, HIF-asparaginyl hydroxylase, also retains its enzymatic function under low oxygen tensions (Stolze et al., 2004). Distribution of oxygen within intracellular compartments may be preserved to maintain enzymes that are critical for adaptations to hypoxia.

In summary, our observations connect hypoxia-dependent establishment of the invasive trophoblast lineage to an epigenetic modulator called KDM3A. HIF signaling serves as an essential intermediary in the process and key regulator of KDM3A expression. KDM3A acts on the epigenetic landscape of target loci controlling development of the invasive trophoblast lineage.

CHAPTER 4:
GENERAL DISCUSSION

I. Model

A summary of our research findings is presented in Figs. 4.1 and 4.2. Fig 4.1 illustrates the role of natural killer cells and hypoxia signaling in trophoblast lineage development. Uterine NK cells regulate vascular development, which impacts oxygen delivery and trophoblast lineage development, ultimately impacting the structural and functional organization of the chorioallantoic placenta.

Fig 4.2 depicts mechanisms of low oxygen signaling in trophoblast invasion. Low oxygen tensions stabilize HIF transcription factors which regulates expression of a number of genes involved in hypoxic adaptations. HIF mediated upregulation of histone demethylase KDM3A epigenetically regulates a subset of hypoxia responsive genes controlling development of the invasive trophoblast lineage.

II. NK Cells Modulate the Timing of Critical Events During Hemochorial Placentation

Strategies have been employed to investigate roles for NK cells during the establishment of pregnancy. These have included genetic mouse models possessing NK cell deficiencies (Croy et al., 2002) and systemic immunodepletion of NK cells using administration of antibodies to asialo GM1 during rat gestation (Chapter 2). The success of the immunodepletion approach is gestation-stage dependent and most effective when administered immediately prior to or concurrent with embryo implantation. From the mouse genetic models we learned that NK cells promote uterine spiral artery remodeling, including decreasing arterial smooth muscle wall thickness and increasing vessel lumen diameter (Guimond et al., 1997). NK cell immunodepletion in the rat results in striking changes in uterine spiral arteries, characterized

Fig. 4.1. Schematic diagram showing the role of NK cells and hypoxia/HIF signaling in the regulation of trophoblast cell differentiation. NK cells regulate uterine vascular development, which impacts oxygen delivery (ΔO_2) and trophoblast lineage decisions, regulating the organisation of the chorioallantoic placenta. Differentiated trophoblast lineages in the labyrinth zone include syncytial trophoblast. Differentiated trophoblast lineages in the junctional zone include trophoblast giant cells, spongiotrophoblast cells, glycogen cells and precursors for invasive trophoblast cells.

Fig4.2. Schematic showing the mechanism of hypoxia signaling mediated KDM3A action and trophoblast invasion. Hypoxia signaling activates KDM3A expression which brings about epigenetic modifications of H3K9 methylation status affecting the invasive behavior of the rat trophoblast cells.

initially by a delay in uterine spiral artery development and progression toward the placenta and subsequently by an acceleration of endovascular invasive trophoblast cell movement and extensive uterine spiral artery remodeling. These physical changes include replacement of the endothelium with endovascular trophoblast cells, their acquisition of a pseudo-endothelial phenotype, the disappearance of smooth muscle cells in the tunica media of the modified uterine spiral artery, distention of uterine spiral artery lumen, and an increased capacity for blood delivery to the placenta. Thus, NK cells possess two apparently contradictory actions in establishing the hemochorial placenta: 1) they promote uterine spiral artery development and remodeling; and 2) they restrain trophoblast-directed uterine spiral artery remodeling. The relative impact of each action on uterine spiral artery remodeling is not equivalent. Invasive trophoblast-directed uterine spiral artery restructuring is far more extensive than NK cell-directed uterine spiral artery restructuring. It is apparent that these opposing efforts are interconnected in an important way. The presence of NK cells delays and reduces the magnitude of trophoblast-directed uterine spiral arterial modifications, which is viewed as a maternally protective adaptation.

Oxygen tension is a key mediator of NK cell actions at the placentation site

NK cells have profound effects on the organization of the placentation site, including the development and function of the invasive trophoblast cell lineage. These cells have been proposed to affect invasive trophoblast cells through their secretion of an assortment of cytokines/chemokines and via direct cell-cell interactions (Lash et al., 2010; Trowsdale and Moffett, 2008; Zhang et al., 2011). Some factors produced by NK cells stimulate invasive properties of trophoblast cells, whereas other NK cell-derived factors inhibit trophoblast invasion. These observations are based exclusively on *in vitro* experimentation and are difficult

to reconcile. A compelling hypothesis has also been proposed for direct NK cell-invasive trophoblast cell engagement (Chazara et al., 2011; Trowsdale and Moffett, 2008). NK cells possess surface receptors termed killer inhibitory receptors (KIRs), which specifically recognize histocompatibility antigens on the surface of trophoblast located at the maternal-fetal interface. This cell-cell interaction modifies NK cell and trophoblast cell function. Two observations support an involvement of NK cell-invasive trophoblast cell adhesion in hemochorial placentation: i) the existence of specific NK cell KIR receptor and histocompatibility antigen isoform combinations in successful pregnancies versus pregnancies afflicted with preeclampsia;(Chazara et al., 2011; Hiby et al., 2010; Hiby et al., 2004) and ii) the observation that endovascular trophoblast invasion and uterine spiral artery remodeling is affected by maternal and paternal histocompatibility antigen combinations (Madeja et al., 2011). These paracrine and cell-cell modes of NK cell action on trophoblast cells may be operative during the establishment of the hemochorial placenta; however, they are probably secondary to the more fundamental action of NK cells on uterine spiral artery development. The latter activities are likely mediated by a myriad of angiogenic and vasoactive factors secreted by NK cells (Zhang et al., 2011).

NK cells regulate uterine spiral artery development and in doing so control oxygen tension at the early placentation site. The absence of NK cells at the maternal-fetal interface results in a transient hypoxia. The effects of NK cell depletion on invasive trophoblast-directed uterine spiral artery remodeling can be mimicked by appropriately timed *in vivo* hypoxia exposure (Rosario et al., 2008). A critical developmental window of sensitivity to *in vivo* hypoxia exposure exists between E8.5 and E9.5 of rat pregnancy. This gestational interval represents a key developmental phase associated with commitment of trophoblast stem

(TS)/precursor cells to differentiated trophoblast cell lineages of the junctional zone versus the labyrinth zone. In addition to the robust extension of endovascular trophoblast invasion deep into the uterine spiral arteries in both NK cell depleted and maternal hypoxia *in vivo* models, the junctional zone also undergoes an expansion relative to the labyrinth zone (Rosario et al., 2008).

III. Hypoxia signaling in trophoblast invasion

TS cell populations are an excellent *in vitro* model system for elucidating mechanisms regulating differentiation (Asanoma et al., 2011; Tanaka et al., 1998). TS cell exposure to a range of oxygen tensions can differentially influence cell proliferation and differentiation (Adelman et al., 2000; Xie et al., 2011; Zhou et al., 2011). The impact of oxygen tension on development of invasive trophoblast lineages from TS cell populations has received little attention. Low oxygen tensions can promote differentiation of TS cells towards junctional zone trophoblast cell lineages. At least some of these hypoxia-stimulated actions are mediated by the HIF transcription factor complex (Adelman et al., 2000). Disruption of HIF signaling impairs TS cell responses to low oxygen and acquisition of an invasive phenotype. Whether these HIF actions are at specific gene loci controlling the invasive trophoblast cell lineage or are indirect through more widespread epigenetic modifications and how they differentially affect TS cell proliferation versus differentiation remain to be determined (Maltepe et al., 2005). Identifying the biology of specific hypoxia-sensitive and HIF target genes should provide insight into the regulatory machinery controlling the invasive trophoblast cell lineage.

Oxygen tension is an important stimulus for placentation. Oxygen tension at the maternal fetal interface changes throughout gestation and is dependent on placental development. Availability of oxygen and developmental variations of oxygen tension can have different

consequences depending on the stage of gestation. Low oxygen tension can be a developmental cue for placental organization and adaptive responses associated with placental development. Alternatively, it can also be a consequence of defective, pathological placentation wherein improper vascular remodeling results in poor placental perfusion and inefficient nutrient delivery. We utilized low oxygen tension as a developmental trigger to study hemochorial placentation and performed global TS cell gene expression analysis to identify targets of low oxygen exposure. We determined that hypoxia promotes a unique differentiated invasive trophoblast lineage, which is characterized by downregulation of trophoblast stem cell associated genes, loss of expression of genes involved cell contacts, upregulation of genes involved in extracellular matrix remodeling, cell movement, and vascular restructuring.

In this study we identified several genes regulated by HIF signaling. Knockdown of the HIF1B, the common binding partner for HIF1A and HIF2A affected hypoxia responses in TS cells. HIF1B has other binding partners so further studies should be conducted to study roles of HIF1A or HIF2A in TS cell adaptations to hypoxia. We envisage modest effects on disruption of HIF1A or HIF2A since it is known that they act on an overlapping set of target genes (Bracken et al., 2006; Hu et al., 2006a; Raval et al., 2005) . This conclusion is further supported from analysis of mouse placentation following mutation of HIF1A, HIF2A, or both HIF1A and HIF2A (Cowden Dahl et al., 2005). ChIP analysis with antibodies specific to HIF1A or HIF2 at known hypoxia responsive target genes such as *Kdm3a* and *Bhlhe40* or alternatively at a genome-wide view using ChIP seq.

Significance of the HIF targets

We have identified hypoxia signature of gene expression in rat TS cells. These genes are reflective of hypoxic adaptations and their functional roles in the process of invasion need to be evaluated. An emerging pattern of gene function in a subset of genes was related to various aspects of invasion. *Mmp12* (Harris, 2010), *Plod2* (Evens et al., 2010; Noda et al., 2012), *Mmp9* (Peters et al., 1999), *Loxl2* (Luo et al., 2012; Wong et al., 2012), *Cul7* (Fu et al., 2010) are known have prominent function of extra cellular matrix remodeling, invasion and metastases. We have observed significant downregulation of expression *Cdh1* which is a hallmark of epithelial mesenchymal transition reported in a number of different cell types (Vicovac and Aplin, 1996). *Bhlhe40* (Hughes et al., 2004; Xie et al., 2011) and *Hand1* (Martindill et al., 2007) are trophoblast differentiation markers and are upregulated and downregulated, respectively in hypoxia exposed TS cells. *Hand1* is a key transcription factor involved in the differentiation of trophoblast giant cell lineage (Hughes et al., 2004; Martindill et al., 2007). Consistent with the known function of *HAND1*, our results demonstrate that hypoxia drives TS cells toward a unique non-giant cell invasive lineage.

The significance of changes in the expression level of each of the genes listed above to acquisition of the invasive trophoblast lineage should be evaluated. Mouse models are potentially available; however, mouse and rat placentation are not equivalent processes. The mouse exhibits shallow trophoblast invasion, which differs dramatically from the extensive trophoblast invasion occurring in the human. Our research shows the importance of utilizing rat models to study trophoblast invasion and uterine spiral artery restructuring. Gene targeting of rat ES cells is a recent technique for generating rat models with a modest success rate (Tong et al., 2011). Other techniques include trophoblast specific knockdown of genes utilizing lentiviral shRNA

delivery(Lee et al., 2009), gene targeting via zinc finger nucleases (Geurts et al., 2009) and use of transposon systems to disrupt gene function (Lu et al., 2007).

Hypoxia dependent global epigenetic changes in rat TS cells

Our approach in trying to understand the molecular mechanisms underlying hypoxia signaling in trophoblast cells is built on the premise that TS cells developmentally experience low oxygen tensions, differentiate and move toward correcting the oxygen deficit. Thus transient exposures to low oxygen, especially *in vitro*, are potentially more physiologically relevant. Chronic exposure to extremely low oxygen tensions can generate pathological responses which will not be reflective of the adaptive response. In our experiments 0.5% oxygen tensions caused a unique differentiated lineage of trophoblast cells possessing an invasive phenotype. Along with the increased invasiveness, we also observed global changes in H3K9 methylation patterns. Biological significance associated with these dramatic global changes in histone marks needs to be deciphered. Genome wide locations of H3K9me1 and H3K9me2 methylation in ambient and hypoxia exposed TS cells will provide information regarding the possible regulatory roles of these histone marks. ChIP sequencing (seq) studies with antibodies to each histone mark will facilitate localization of relevant genomic regions and their correlation with potential regulatory mechanisms controlling adaptations to hypoxia and invasive trophoblast lineage development. A similar strategy has been used to dissect hippocampal gene networks controlling responses to stressors. Hippocampal H3 histone methylation, especially H3K9me3 is regulated by acute and chronic stress in the rat (Hunter et al., 2009). ChIP seq localized stress induced H3K9me3 enrichment to sites responsible for silencing endogenous retroviral elements (Hunter et al., 2012).

In our analysis we observed global changes in histone H3K9 methylation. Others have observed that hypoxia exposure results in global epigenetic changes in histone methylation and acetylation (Johnson et al., 2008). Expansions of repressive H3K27 trimethylation marks and activating H3K4 trimethylation marks following hypoxia have been observed. Parameters of hypoxia exposure (duration and concentration) and cell type should be considered in further investigations.

KDM3A as a mediator of hypoxia dependent adaptations in rat TS cells

Low oxygen tension stabilizes HIF transcription factors, which control cellular adaptations at a transcriptional level and through regulation of epigenetic modifiers. The latter represents a global mechanism of regulation extending the breadth of HIF influence. In TS cells KDM3A is rapidly upregulated in response to hypoxia in a HIF-dependent manner. KDM3A is a histone H3K9 demethylase and controls the expression of a subset of hypoxia/HIF responsive genes and development of the invasive trophoblast lineage. We expect that KDM3A directs differentiation through its actions at specific loci throughout the genome. Again a ChIP seq approach for identifying enrichment of KDM3A at specific genomic sites will be informative.

Histone H3K9me1 and H3K9me2 enrichment at the *Mmp12* locus in TS cells was influenced by hypoxia exposure. Whether this event is dependent upon the activities of KDM3A is unknown. Additionally, the breadth of KDM3A action on the distribution of genome-wide changes in H3K9me1 and H3K9me2 marks is unknown. Combining a ChIP seq analysis of histone H3K9 methylation with genome-wide KDM3A localization will help address this uncertainty.

Activation of HIF signaling pathways under low oxygen tensions upregulate a variety of other JmJc domain containing demethylases which include Kdm4b, Kdm4c, Jarid1b (Krieg et al., 2010; Pollard et al., 2008). These demethylases act on different histone methylation marks. Kdm4 family of demethylases act on H3K93me/2me and H3k363me/2me and Jarid1b acts on H3K4-2me/3me (Mosammaparast and Shi, 2010). Presumably these different JmJc domain containing demethylases possess unique as well as overlapping targets and contribute to a complex histone H3 methylome characteristic of cells undergoing adaptations to hypoxia. The conditions of our experimentation were not associated with dramatic changes in KDM4 or JARID1B demethylases.

IV. Relevance of our research to human placentation and human pregnancy disorders

Pregnancy associated disorders

There are a number of pregnancy associated disorders in humans which are associated with improper trophoblast development and differentiation leading to inadequate trophoblast invasion and vascular remodeling. Preeclampsia syndrome is one of the most common placental pathology occurring in 3-5% of first pregnancies (Kanasaki and Kalluri, 2009). It is characterized by mild to severe maternal hypertension and proteinuria around midgestation and/or mild to severe intrauterine fetal growth restriction. Preeclampsia is one of the leading causes of maternal and fetal death during pregnancy. Poor trophoblast invasion leads to insufficient perfusion of the placenta which triggers placental hypoxia. This causes upregulation of placental anti-angiogenic factors like soluble Flt1 (Levine et al., 2004; Maynard et al., 2003) which results in the angiogenic factor imbalance and subsequent disruption of vascular

endothelium and maternal cardiovascular system (Maynard and Karumanchi, 2011; Powe et al., 2011). Possible cures include premature delivery of the baby and the placenta.

IUGR is another pregnancy associated disorder which is characterized by small for gestational age babies (Scifres and Nelson, 2009). Causes of the disease can be traced back to improper placental development as well as shallow trophoblast invasion leading to inefficient vascular remodeling. IUGR can result in developmentally growth retarded babies, disability and even fetal death. Research has shown that placental environment can play a huge role in determining adult life health disorders like hypertension, cardiovascular disease, renal diseases and diabetes to name a few (Barker, 2007; Thornburg et al., 2010a; Thornburg et al., 2010b).

Uterine NK cells and pregnancy associated disorders:

Recent studies have implicated role of decidual NK cells in vascular smooth muscle cell apoptosis (Fraser et al., 2012). Studies show in a co-culture *in vitro* model that decidual NK cells from normal pregnancies can initiate trophoblast invasion disrupting vascular endothelium, however when decidual NK cells obtained from high resistance pregnancies are co-cultured with trophoblast cells, impaired vascular remodeling and reduced invasiveness is observed. (Fraser et al., 2012). Peripheral NK cell number has been shown to stay unchanged in preeclamptic pregnancies, aberrant NK cell expression and increased NKG2A- and NKG2C surface receptors have been observed in preeclampsia (Bachmayer et al., 2009).

NK cells exhibit a polarity in their production of cytokines during pregnancy. Similar to other types of immune cells, NK cells also shift from Th1 to Th2 cytokines as pregnancy progresses. Persistence of NK cell Th1 production (e.g. Tumor Necrosis Factor α) is associated with a higher incidence of abortions.

Elevated NK cell cytotoxicity is also associated with implantation failure after *in vitro* fertilization and embryo transfer and in women experiencing recurrent pregnancy loss (Fukui et al., 2011). Correlations have been made between cell surface expression of receptors in peripheral NK cells and pregnancy outcomes. A significant decrease in the percentage of CD56^{bright}/NKp46⁺ cells is detected in preeclamptic patients 3-4 months before the onset of preeclampsia (Fukui et al., 2012).

Finally, increased numbers of uterine NK cells have been observed at the placental interface in preeclamptic (Reister et al., 2006) and IUGR (Williams et al., 2009) pregnancies. Furthermore, excessive LIF production by NK cells in preeclamptic pregnancies has been associated with reductions in matrix metalloprotease synthesis by extravillous trophoblast (Reister et al., 2006).

Hypoxia signaling and pregnancy associated disorders:

Role of HIF transcription factors in preeclampsia remains debatable. This is largely due to the fact that hypoxia signaling seems to be playing instructive role in shaping of the placenta during early gestation. The placenta develops under low oxygen tensions until the uterine maternal vasculature is remodeled by invading trophoblast cells (Rodesch et al., 1992). HIF1A is highly expressed in early gestation trophoblast cells and is subsequently downregulated around 9 weeks of gestation (Caniggia et al., 2000). However this issue is complex. Failures in placentation caused by shallow trophoblast invasion result in impaired placental perfusion, and trigger chronic hypoxia signaling, which leads to pathogenesis.

HIF1A expression may be upregulated in preeclampsia. *HIF-1A* RNA expression in maternal plasma is increased in pregnant women with preeclampsia and IUGR (Ashur-Fabian et

al., 2012). A role for HIF-1A in the pathogenesis of preeclampsia has also been determined from investigation of placentation in women residing at high altitudes experiencing chronic hypoxia (Zamudio et al., 2007). Preeclampsia incidence is higher in these women and their placentas show elevated HIF1A expression (Zamudio et al., 2007). A number of downstream effectors of HIF signaling involved in the pathogenesis of preeclampsia have been identified. Anti-angiogenic factors like Endothelin (Yamashita et al., 2001), sFlt1 (Nevo et al., 2008; Nevo et al., 2006), Endoglin (Yinon et al., 2008) are hypoxia responsive and significantly upregulated in IUGR and preeclamptic placentas. Urocortin peptides are also HIF targets and elevated in preeclampsia (Imperatore et al., 2010). Urocortin peptides are known to be local regulators of myometrial contractility (Florio et al., 2004).

Stabilization is a key process regulating HIF activities. Early onset preeclamptic placentas exhibit decreased proteosomal degradation of HIF-1A (Rajakumar et al., 2006; Rajakumar et al., 2008). PHD2 and FIH are involved in stabilization and activation of HIF transcription factors and have been shown to be downregulated in early onset preeclampsia syndrome (Rolfo et al., 2010). Manifestation of the pathological features of preeclamptic disease is linked to an impaired ability of the trophoblast cells to respond and adapt to gestation dependent variations in oxygen tensions (Tal, 2012).

Hypoxia responsive invasion and vascular remodeling related genes in preeclampsia and IUGR

Several of the hypoxia responsive genes have been investigated in preeclampsia, including *Plau*, *Mmp9*, *Comt*, *Cul7*, *Cdh1*, *FasI*, *Glut1*, *Vegfa*. PLA_U is an established biomarker of Preeclampsia and complicated hypertensive pregnancies. Plasma concentrations of PLA_U are

downregulated in severe preeclamptic pregnancies and IUGR (Koh et al., 1993; Lindoff and Astedt, 1994), as is cell surface PLA₂ activity (Graham and McCrae, 1996). Although the significance of MMP9 in the etiology of preeclampsia syndrome is unknown, increased MMP9 levels have been observed in preeclamptic placentas (Wang et al., 2010). Two methoxy estradiol (2ME) is generated by the enzymatic activities of COMT. Plasma concentrations of 2ME are low in preeclamptic pregnancies (Perez-Sepulveda et al., 2012; Seol et al., 2012). The Val158Met COMT polymorphism is associated with increased COMT activity and a decreased risk to develop preeclampsia, suggesting a protective role against preeclampsia. Conversely, a low COMT activity haplotype has been linked to higher risk of recurrent preeclampsia (Kanasaki et al., 2008; Roten et al., 2011).

The CUL7 gene is upregulated in IUGR and preeclampsia associated with IUGR, with extensive promoter hypomethylation observed in IUGR placentae (Gascoin-Lachambre et al., 2010). CDH1 plays an important role in cell-cell adhesion and epithelial to mesenchymal transitions. Variations in the expression of CDH1 and its repressor SNAIL are observed in preeclamptic placentas (Brown et al., 2005). FASL, a regulator of apoptosis, is significantly down regulated in placental villi of preeclampsia patients (Neale and Mor, 2005). Serum FASL concentrations have also been used as biomarker of the preeclampsia (Laskowska et al., 2006). IUGR is also associated with reduced glucose transport to the fetus and decreased expression of placental GLUT1 (Zamudio et al., 2010). In pregnancies with adverse outcomes, (gestational hypertension, small for gestational age and pre-term birth) reduced VEGF family of angiogenic factor mRNAs is observed (Andraweera et al., 2013). In a recent bioinformatics study accessing publicly available preeclampsia databases, VEGF family along with its receptors have found significant correlation with the disease (Tejera et al., 2012). Numerous polymorphisms

associated with VEGFA are correlated to pregnancies complicated with adverse outcomes (Andraweera et al., 2013; Andraweera et al., 2011).

KDM3A in the human placenta

Knowledge of the role of KDM3A in human trophoblast is limited. KDM3A can be localized in the first trimester trophoblast samples, particularly strong immunostaining was observed in the extravillous trophoblast columns (Chapter 3; **Fig 3.8C**). Its expression can also be observed in the Bewo cell line and upregulation of *Kdm3a* can be observed on hypoxia exposure both at transcript and protein levels (Chapter 3; **Fig 3.8 A&B**). Thorough investigations are needed to evaluate the role of KDM3A in human trophoblast cells. First trimester trophoblast may be the best choice to understand the role of KDM3A in the process of low oxygen signaling dependent trophoblast invasion. Although the potential for mechanistic studies on role of KDM3A in human placentation is limited, KDM3A expression, activity and polymorphisms can be investigated in normal as well as complicated pregnancy outcomes.

V. Overview of the importance of the work

We have identified the importance of maternal environment on development of placentation. Our work identified uterine NK cells as regulators of placentation, particularly fine tuning oxygen availability at the developing placentation site. Availability of oxygen acted as a developmental cue for the organization of chorioallantoic placentation and the process of invasive trophoblast lineage development. In the later part of the work, we have identified mechanisms underlying hypoxia signaling. These efforts started with gene profiling experiments in rat TS cells and led to the identification of KDM3A, a key mediator of hypoxia dependent epigenetic reorganisation and development of the invasive trophoblast lineage. This knowledge

derived from the rat placentation model can be utilized to elucidate specific mechanisms underlying regulation of hemochorial placentation in normal and pathologic pregnancies.

Cellular Growth and Proliferation	cytostasis of tumor cell lines	5.90E-03	Decreased	-2.587	BCL6,BCR,BHLHE40,BMP4,BMPR1A,CDCA8,CDH1,CDKN1B,EGR1,GPI,IRF2,LTBP1,MAPK14,NQO1,PRMT1,RBPJ,SMAD2,TOP2A,TTC5

Cell Death and Survival	cell death of cancer cells	9.40E-03	Increased	2.102	AKT1S1,BIK,BMP4,BOK,CASP6,CDH1,CDKN1B,CHEK1,DDIT3,EGLN3,EIF2AK3,FASLG,FASN,FOXO4,HIF1A,JUN,MAP3K1,MAPK14,MMP9,MYC,NCOA3,PAWR,PLK1,PRKCD,RAF1,RALB,SPHK1,TFAP2A,VEGFA,VHL
Tumor Morphology	cell death of cancer cells	9.40E-03	Increased	2.102	AKT1S1,BIK,BMP4,BOK,CASP6,CDH1,CDKN1B,CHEK1,DDIT3,EGLN3,EIF2AK3,FASLG,FASN,FOXO4,HIF1A,JUN,MAP3K1,MAPK14,MMP9,MYC,NCOA3,PAWR,PLK1,PRKCD,RAF1,RALB,SPHK1,TFAP2A,VEGFA,VHL
Post-Translational Modification	ubiquitination of protein	1.06E-02	Increased	2.213	ARIH1,ARIH2,BAG5,CDC34,DDB1,DNAJB2,FBXO22,FBXO6,GCLC,GTPBP4,HDAC6,HSPBP1,MAP3K1,MAPT,NDFIP2,NUB1,PLK1,PSMC4,RLIM,RNF13,RNF139,RNF4,UBE2C,UBE2T,UBE4B,UBR1 (includes EG:197131),UBR2 (includes EG:224826),UHRF2,VHL,WWP1
Cardiovascular Disease	damage of artery	1.12E-02	Decreased	-2.000	EFEMP2,PLAT,PLAU,PLOD1
Cell Cycle	contact growth inhibition of tumor cell lines	1.25E-02	Decreased	-2.287	BMP4,BMPR1A,CDH1,EGR1,GPI,LTBP1,MAPK14,SMAD2,TOP2A,TTC5
Cellular Growth and Proliferation	contact growth inhibition of tumor cell lines	1.25E-02	Decreased	-2.287	BMP4,BMPR1A,CDH1,EGR1,GPI,LTBP1,MAPK14,SMAD2,TOP2A,TTC5
Cell-To-Cell Signaling and Interaction	contact growth inhibition of tumor cell lines	1.25E-02	Decreased	-2.287	BMP4,BMPR1A,CDH1,EGR1,GPI,LTBP1,MAPK14,SMAD2,TOP2A,TTC5
Developmental Disorder	craniofacial abnormality	1.40E-02	Decreased	-2.402	ALKBH1,BMPR1A,CITED2,GADD45A,GDF1,HSD17B2,INSIG1,INSIG2,JMJD6,LAMC1,LMNB1,LMNB2,MSX1,ORC1 (includes EG:18392),ORC6 (includes EG:23594),PDGFA,RAF1,RBPJ,RGMA,SMAD2,SOS1,SPHK1,TCOF1,TFAP2A
Connective Tissue Disorders	craniofacial abnormality	1.40E-02	Decreased	-2.402	ALKBH1,BMPR1A,CITED2,GADD45A,GDF1,HSD17B2,INSIG1,INSIG2,JMJD6,LAMC1,LMNB1,LMNB2,MSX1,ORC1 (includes EG:18392),ORC6 (includes EG:23594),PDGFA,RAF1,RBPJ,RGMA,SMAD2,SOS1,SPHK1,TCOF1,TFAP2A
Skeletal and Muscular Disorders	craniofacial abnormality	1.40E-02	Decreased	-2.402	ALKBH1,BMPR1A,CITED2,GADD45A,GDF1,HSD17B2,INSIG1,INSIG2,JMJD6,LAMC1,LMNB1,LMNB2,MSX1,ORC1 (includes EG:18392),ORC6 (includes EG:23594),PDGFA,RAF1,RBPJ,RGMA,SMAD2,SOS1,SPHK1,TCOF1,TFAP2A
Cellular Development	differentiation of stem cells	1.86E-02	Decreased	-2.263	BHLHE41,BMP4,EIF4G2,HIF1A,HSP90B1,ID2,ID3,IL6ST,JUN,KLF4,LIN28A,MLLT11,MSX1,MYC,RBPJ,RNF2,SIPR1,SFN,SMARCB1,VEGFA,WNT4,WTR1

Cell Cycle	cytokinesis	2.71E-02	Decreased	-2.534	AURKA,CCNB1,CCNG1,CDC20 (includes EG:107995),CIT,ECT2,GADD45A,IVN S1ABP,KIF20A,KIF23,PLK1,RALB,R HOB,SETD8,SRC,SSRP1,TOP2A
Cellular Movement	cytokinesis	2.71E-02	Decreased	-2.534	AURKA,CCNB1,CCNG1,CDC20 (includes EG:107995),CIT,ECT2,GADD45A,IVN S1ABP,KIF20A,KIF23,PLK1,RALB,R HOB,SETD8,SRC,SSRP1,TOP2A
Cell Death and Survival	apoptosis of keratinocyte cancer cell lines	3.04E-02	Increased	2.186	BCL3,FASLG,IER3,NQO1,RHOB
Cellular Movement	invasion of epithelial cell lines	3.04E-02	Increased	2.201	CDH1,IER3,ITGA3,MMP9,PLAU

Fig.A1.1 Selective canonical pathways analyzed by Ingenuity Pathway Analysis. The bar graph represents a subset of significantly represented canonical signaling pathways when rat TS cells are exposed to 0.5% O₂ analyzed by Ingenuity Pathway analysis.

Table A1.2. Genes represented in canonical pathways by Ingenuity Pathway Analysis.

Ingenuity Canonical Pathways	-log(p-value)	Ratio	Molecules
Glycolysis I	4.33E00	2E-01	PGK1,Eno1/Eno1-ps1,GPI,PGAM1,ENO2,ALDOA,PFKL,Tpi1 (includes others),ALDOC
Protein Ubiquitination Pathway	3.01E00	1.23E-01	USP24,PSMA3,ANAPC1/LOC100286979,CDC20 (includes EG:107995),HSPA1A/HSPA1B,PSMB10,UBR2 (includes EG:224826),UBR1 (includes EG:197131),DNAJC3,DNAJB2,PSMB8,USP39,PSMC5,USP48,HSP90B1,PSMC6,USP10,DNAJB1,USP15,UBE4B,USP27X,PSMC4,THOP1,USP1,DNAJB9,DNAJC11,PSME1,DNAJC5,PSMD12,CDC34,DNAJB6,VHL,UBE2C
Gluconeogenesis I	2.85E00	1.4E-01	PGK1,Eno1/Eno1-ps1,GPI,PGAM1,ENO2,ALDOA,ALDOC
Mouse Embryonic Stem Cell Pluripotency	2.49E00	1.52E-01	IL6ST,RAF1,ID2,PIK3CA,BMP4,GRB2,RRAS,BMPR2,ID3,MYC,ID1,MAPK14,MAP3K7 (includes EG:26409),BMPR1A,SOS1
Renal Cell Carcinoma Signaling	2.39E00	1.62E-01	VEGFA,RAF1,PIK3CA,JUN,SLC2A1,GRB2,RRAS,SOS1,EGLN3,HIF1A,RAP1A,VHL
ATM Signaling	2.37E00	1.8E-01	RAD51,SMC3,JUN,GADD45B,MAPK14,GADD45A,H2AFX,CCNB2,ATF4,CHEK1,CCNB1
Glycogen Biosynthesis II (from UDP-D-Glucose)	2.25E00	2.5E-01	GYS1,GYG1,GBE1
Endoplasmic Reticulum Stress Pathway	2.16E00	2.78E-01	DNAJC3,ATF4,ATF6,EIF2S1,EIF2AK3
Estrogen Receptor Signaling	2.05E00	1.32E-01	RAF1,SRC,TAF11 (includes EG:309638),GRB2,GTF2F2,RRAS,TBP,MED21,GTF2F1,TAF13 (includes EG:310784),NCOA3,MED27,THRAP3,SOS1,POLR2I,TAF2 (includes EG:170844),MED10,GTF2H3
HIF1 α Signaling	2.05E00	1.39E-01	PIK3CA,SLC2A1,RRAS,HIF1A,SLC2A3,VEGFA,EGLN1,JUN,MAPK14,EGLN3,MMP12,APEX1,MMP9,MMP17,VHL
p53 Signaling	2.04E00	1.35E-01	PIK3CA,GADD45B,C12orf5,CHEK1,CCNG1,CASP6,JUN,MAPK14,GADD45A,STAG1,BBC3,GNL3,SFN
NRF2-mediated Oxidative Stress Response	1.97E00	1.2E-01	RAF1,PIK3CA,RRAS,MAP3K1,NQO1,DNAJC3,GCLC,DNAJB2,DNAJB9,MAFF,DNAJC11,JUN,DNAJC5,MAPK14,MAP3K7 (includes EG:26409),PRKCD,ATF4,CDC34,DNAJB6,DNAJB1,GCLM,FKBP5,EIF2AK3
PDGF Signaling	1.84E00	1.41E-01	MYC,RAF1,SRC,PIK3CA,JUN,GRB2,RRAS,PDGFA,MAP3K1,SOS1,SPHK1,INPP5K
Assembly of RNA Polymerase III Complex	1.8E00	2.5E-01	GTF3C4,GTF3C3,TBP,GTF3A
Regulation of eIF4 and p70S6K Signaling	1.8E00	1.03E-01	RAF1,PIK3CA,GRB2,RRAS,EIF2B3,EIF4G3,PAIP2,ITGA3,EIF2S1,EIF4EBP1,RPS24,MAPK14,EIF4G2,EIF1AX,PPM1J,SOS1,EIF2B1,PPP2R1B
Oleate Biosynthesis II (Animals)	1.76E00	1.58E-01	SCD,UFPS2,Scd2

Hypoxia Signaling in the Cardiovascular System	1.74E00	1.52E-01	VEGFA,P4HB,HSP90B1,JUN,NQO1,ATF4,HIF1A,CDC34,VHL,UBE2C
VEGF Signaling	1.72E00	1.31E-01	RAF1,PIK3CA,GRB2,RRAS,EIF2B3,HIF1A,EIF2S1,VEGFA,EIF1AX,SOS1,EIF2B1,SFN,ACTN1
Role of Oct4 in Mammalian Embryonic Stem Cell Pluripotency	1.55E00	1.56E-01	CASP6,KDM5B,TDH,PCGF6,PHC1,SH3GLB1,FBXO15
Cell Cycle Regulation by BTG Family Proteins	1.46E00	1.67E-01	PRMT1,PPM1J,BTG2,E2F5,PPP2R1B,CCRN4L
Cardiomyocyte Differentiation via BMP Receptors	1.45E00	2E-01	BMP4,BMPR1A,MAP3K7 (includes EG:26409),BMPR2
PI3K/AKT Signaling	1.41E00	1.04E-01	RAF1,PIK3CA,GRB2,RRAS,ITGA3,EIF4EBP1,HSP90B1,GYS1,PPM1J,SOS1,MAP3K8,CDKN1B,INPP5K,SFN,PPP2R1B
ERK/MAPK Signaling	1.29E00	9.71E-02	SRC,RAF1,PIK3CA,PLA2G12A,GRB2,RRAS,PPP1R3C,ITGA3,RAP1A,EIF4EBP1,KSR1,MYC,ELF3,PPP1R10,DUSP1,PRKCD,PPM1J,SOS1,ATF4,PPP2R1B
ErbB2-ErbB3 Signaling	1.28E00	1.33E-01	MYC,RAF1,PIK3CA,JUN,GRB2,RRAS,SOS1,CDKN1B
Cell Cycle: G2/M DNA Damage Checkpoint Regulation	1.27E00	1.46E-01	GADD45A,TOP2A,CCNB2,PLK1,SFN,CHEK1,CCNB1
BMP signaling pathway	1.25E00	1.25E-01	RAF1,JUN,BMP4,MAPK14,BMPR1A,GRB2,RRAS,MAP3K7 (includes EG:26409),SOS1,BMPR2
TGF- β Signaling	1.24E00	1.24E-01	SMAD2,RAF1,JUN,BMP4,MAPK14,BMPR1A,GRB2,RRAS,MAP3K7 (includes EG:26409),SOS1,BMPR2
AMPK Signaling	1.21E00	9.64E-02	CAB39,SRC,PIK3CA,CPT1A,PFKL,PPM1D,EIF4EBP1,GYS1,MAPK14,PPM1J,FASN,AK4,ACACA,HLTF,PPP2R1B,PPAT
Cyclins and Cell Cycle Regulation	1.18E00	1.12E-01	HDAC6,CCNA2,RAF1,PPM1J,E2F5,CCNB2,CDKN1B,PPP2R1B,HDAC5,CCNB1
Assembly of RNA Polymerase II Complex	1.13E00	1.25E-01	TAF11 (includes EG:309638),TBP,GTF2F1,TAF13 (includes EG:310784),TAF2 (includes EG:170844),POLR21,GTF2H3
tRNA Charging	1.11E00	7.41E-02	TARS2,MARS2,DARS,HARS,HARS2,FARSB
Fatty Acid β -oxidation I	1.1E00	1.11E-01	ECI2,AUH (includes EG:11992),SLC27A1,SLC27A3,ECI1
Ceramide Signaling	1.08E00	1.14E-01	RAF1,PIK3CA,JUN,RRAS,PPM1J,MAP3K1,SPHK1,S1PR1,PPP2R1B,KSR1
Hereditary Breast Cancer Signaling	9.95E-01	1.02E-01	PIK3CA,GADD45B,RRAS,HDAC5,CHEK1,CCNB1,RAD51,HDAC6,GADD45A,H2AFX,SFN,HLTF,POLR21
p38 MAPK Signaling	9.8E-01	1.03E-01	IL33,IL1R2,MYC,MAPK14,PLA2G12A,DDIT3,DUSP1,MAP3K7 (includes EG:26409),MAPT,ATF4,FASLG,IRAK2
Aldosterone Signaling in Epithelial Cells	9.76E-01	9.52E-02	RAF1,PIK3CA,HSPA1A/HSPA1B,PDIA3,DNAJC3,DNAJB2,DNAJB9,DNAJC11,HSP90B1,DNAJC5,DUSP1,PRKCD,SOS1,DNAJB6,DNAJB1,PI4KA

Endometrial Cancer Signaling	9.67E-01	1.23E-01	MYC,RAF1,PIK3CA,CDH1,GRB2,RRAS,SOS1
Paxillin Signaling	9.66E-01	9.91E-02	SRC,ITGAE,PIK3CA,MAPK14,GRB2,RRAS,SOS1,ITGA3,ITGA7,ACTN1,GIT2
Glioblastoma Multiforme Signaling	9.58E-01	9.15E-02	RAF1,SRC,PIK3CA,GRB2,RRAS,PDGFA,PDIA3,NF2,MYC,RHOB,PRKCD,SOS1,E2F5,WNT4,CDKN1B
PTEN Signaling	9.46E-01	9.63E-02	FOXO4,RAF1,PIK3CA,SHARPIN,GRB2,RRAS,BMPR2,ITGA3,BMPR1A,SOS1,INPP5K,CDKN1B,FASLG
Glucose and Glucose-1-phosphate Degradation	9.3E-01	9.09E-02	HK1,PGM1
Role of NANOG in Mammalian Embryonic Stem Cell Pluripotency	9.13E-01	9.65E-02	IL6ST,RAF1,PIK3CA,RIF1 (includes EG:295602),BMP4,BMPR1A,GRB2,RRAS,SOS1,BMPR2,WNT4
14-3-3-mediated Signaling	9.04E-01	1.03E-01	RAF1,SRC,PIK3CA,JUN,GRB2,RRAS,PDIA3,PRKCD,MAPT,CDKN1B,SFN,AKT1S1
Transcriptional Regulatory Network in Embryonic Stem Cells	8.58E-01	1.25E-01	RIF1 (includes EG:295602),KAT6A,HAND1,EOMES,SET
Glycogen Degradation II	8.3E-01	1.25E-01	PGM1,PYGL
Sertoli Cell-Sertoli Cell Junction Signaling	8.19E-01	8.72E-02	RAF1,SRC,TJP2,CLDN15,RRAS,MAP3K1,ITGA3,MPP6 (includes EG:35343),F11R,CDH1,JUN,MAPK14,CLDN4,MAP3K7 (includes EG:26409),MAP3K8,ACTN1,PVRL2
Cell Cycle: G1/S Checkpoint Regulation	7.97E-01	1.06E-01	HDAC6,MYC,PAK1IP1,E2F5,GNL3,CDKN1B,HDAC5
Chronic Myeloid Leukemia Signaling	7.95E-01	9.52E-02	HDAC6,MYC,RAF1,PIK3CA,GRB2,RRAS,SOS1,E2F5,CDKN1B,HDAC5
VEGF Family Ligand-Receptor Interactions	7.83E-01	9.52E-02	VEGFA,RAF1,PIK3CA,PLA2G12A,GRB2,RRAS,PRKCD,SOS1
FLT3 Signaling in Hematopoietic Progenitor Cells	6.8E-01	1.05E-01	RAF1,PIK3CA,MAPK14,GRB2,RRAS,SOS1,ATF4,EIF4EBP1
Molecular Mechanisms of Cancer	6.14E-01	7.69E-02	RAF1,PIK3CA,BMP4,APH1B,BMPR2,HIF1A,CHEK1,MYC,CASP6,JUN,RHOB,BBC3,BMPR1A,MAP3K7 (includes EG:26409),SOS1,E2F5,FASLG,SMAD2,SRC,RRAS,GRB2,RALB,AURKA,RAP1A,CDH1,MAPK14,PRKCD,RBPJ,CDKN1B
Lipid Antigen Presentation by CD1	6.1E-01	8.7E-02	PDIA3,PSAP
Fatty Acid Activation	6.1E-01	1.05E-01	SLC27A1,SLC27A3
Leukocyte Extravasation Signaling	5.48E-01	8.12E-02	SRC,PIK3CA,CLDN15,RAP1A,F11R,WIPF1,MAPK14,CLDN4,PRKCD,FER,MMP12,CTTN,ACTN1,MMP9,MMP17,ARHGAP8/PRR5-ARHGAP8
Glioma Signaling	5.38E-01	8.04E-02	RAF1,PIK3CA,Calm1 (includes others),GRB2,RRAS,PDGFA,PRKCD,SOS1,E2F5
FAK Signaling	5.29E-01	7.92E-02	RAF1,SRC,PIK3CA,GRB2,RRAS,SOS1,ITGA3,GIT2

Arsenate Detoxification I (Glutaredoxin)	5.17E-01	5E-02	GLRX2
Prostate Cancer Signaling	5.1E-01	8.16E-02	RAF1,PIK3CA,HSP90B1,GRB2,RRAS,SOS1,ATF4,CDKN1B
LPS-stimulated MAPK Signaling	4.8E-01	8.54E-02	RAF1,PIK3CA,JUN,MAPK14,RRAS,MAP3K7 (includes EG:26409),PRKCD
Germ Cell-Sertoli Cell Junction Signaling	4.75E-01	7.93E-02	SRC,PIK3CA,RRAS,MAP3K1,ITGA3,CDH1,MAPK14,RHOB,MAP3K7 (includes EG:26409),FER,MAP3K8,ACTN1,PVRL2
ErbB Signaling	4.74E-01	9.2E-02	RAF1,PIK3CA,JUN,MAPK14,GRB2,RRAS,PRKCD,SOS1
Breast Cancer Regulation by Stathmin1	4.73E-01	7.73E-02	RAF1,PIK3CA,Calm1 (includes others),GRB2,RRAS,PPP1R3C,GNB4,STMN1,PPP1R10,PPM1J,PRKCD,SOS1,E2F5,GNG2,CDKN1B,PPP2R1B
Colorectal Cancer Metastasis Signaling	4.73E-01	7.39E-02	IL6ST,SMAD2,SRC,PIK3CA,GRB2,RRAS,MYC,VEGFA,GNB4,APPL1,CDH1,JUN,RHOB,SOS1,WNT4,GNG2,MMP12,MMP9,MMP17
Mechanisms of Viral Exit from Host Cells	4.69E-01	8.89E-02	PRKCD,SH3GLB1,LMNB2,LMNB1
Acute Myeloid Leukemia Signaling	4.62E-01	8.54E-02	MYC,RAF1,PIK3CA,GRB2,RRAS,SOS1,EIF4EBP1

Table A2.1. Genes upregulated on hypoxia exposure

Affymetrix ID	Gene Title	Gene Symbol	Ave amb sig int	Ave hypox sig int	hypox/ amb
1373108_at	protein phosphatase 1, regulatory (inhibitor) subunit 3C	Ppp1r3c	40	1668	41.298

APPENDIX B

Curriculum Vitae

Damayanti Chakraborty

Personal Information:

Born: 3rd March; 1982, Calcutta, India

Present position: Graduate Student, Department of Pathology and Laboratory Medicine,
University of Kansas Medical Center

Contact Information:

Department of Pathology and Laboratory Medicine,
University of Kansas Medical Center

39th and Rainbow Boulevard

Kansas City, KS 66160

Laboratory Phone: (913) 588-5690

Administrative Office Phone: (913) 588-5774

Fax: (913) 588-8287

Email: dchakraborty@kumc.edu

Education:

B.S	2003	Physiology	Presidency College, Calcutta University, Calcutta, India
M.S	2005	Biochemistry	Calcutta University, Calcutta, India
Ph.D.	2006- 2013	Pathology/ Reproductive Biology	Department of Pathology and Laboratory Medicine, University of Kansas Medical Center, Kansas City, Kansas

Awards:

1. American Heart Predoctoral Fellowship, January-2010 – December-2011.
2. Biomedical Training Research Program Fellowship, University of Kansas Medical Center, July-2009 – June-2010.
3. First position in Basic Science Session 3, Student Research Forum, April-2010.
4. University of Kansas Medical Center student travel award 2008, 2010, 2012.

5. Best poster award, 4th Annual Gilbert S. Greenwald Symposium on Reproduction, Kansas City, Missouri, October 5-6, 2007.
6. Best poster award in International Conference on Male reproduction and infertility, Bangalore, India, September 16-18, 2005.
7. Qualified for lectureship in National Eligibility Test (NET) conducted by University Grants Commission (U G C), India, 2005.
8. Awarded scholarship by Education Directorate, Government of West Bengal, India for merit in Bachelor of Science Examinations, 2005.

Research Interests:

I am very interested to study epigenetic regulation of cell fate decisions particularly histone modifications underlying the stem and differentiation states and how delicate balance of different histone modifying enzymes governs these phenomena.

Research Support:

1. Recipient of a Predoctoral Fellowship from the American Heart Association, AHA Identification No. 10PRE2640133, January 1, 2010 to December 31, 2012. Project Title: Role of natural killer cells in uteroplacental vascular adaptations.
2. Recipient of Biomedical Training Research Program Fellowship, University of Kansas Medical Center, July-2009 – Dec-2009. Project Title: Role of natural killer cells in uteroplacental adaptations.

Oral Presentations:

1. **Chakraborty D**, Rumi MAK, Konno T, Asanoma K, and Soares MJ. Natural killer cells direct hemochorial placentation. Society for Gynecologic Investigation, Florida, March 16-19, 2011
2. **Chakraborty D**, Rumi MAK, Konno T, Asanoma K, and Soares MJ. Natural killer cell directed uterine spiral artery remodeling impacts oxygen delivery and trophoblast lineage decisions. Oral presentation at the Gordon Research Conference on Reproductive Tract Biology, Proctor Academy, Andover, New Hampshire, Aug 15-20, 2010.
3. **Chakraborty D**, Rumi MAK, Konno T, Asanoma K, and Soares MJ. Role of natural killer cells in uteroplacental vascular adaptations. Student Research Forum, University of Kansas Medical Center, Kansas City, Kansas, April 15-16, 2010.

4. **Chakraborty D**, Konno T, and Soares MJ. Role of uterine natural killer cells in uteroplacental adaptations. Student Research Forum, University of Kansas Medical Center, Kansas City, Kansas, April 9-10, 2009.

Book Chapters:

1. Varghese AC, **Chakraborty D**, and Bhattacharyya AK. Cryopreservation of Ovarian Tissue. In "The Laboratory Manual of Assisted Reproductive Technology" Editor: Rao, K A , Jaypee Brothers Medical Publishers, New Delhi, Chapter 22; pp 256-268.
2. **Chakraborty D** and Kumar TR. Murine models for reproduction. In "Sourcebook of models for biomedical research" Editor: Conn, PM, Humana Press, New Jersey, Chapter 44; pp: 411-423, 2008.

Publications:

1. Soares MJ, **Chakraborty D**, Renaud SJ, Kubota K, Bu P, Konno T, and Rumi MA. Regulatory pathways controlling uterine spiral artery remodeling. *Journal of Reproduction and Development*, 2012; 58:283-87.
2. **Chakraborty D**, Rumi MA, and Soares MJ. NK cells, hypoxia and trophoblast cell differentiation., *Cell Cycle*. 2012 Jul 1;11(13):2427-30.
3. Soares MJ, **Chakraborty D**, Karim Rumi MA, Konno T, and Renaud SJ. Rat placentation: an experimental model for investigating the hemochorial maternal-fetal interface. *Placenta*. 2012 Apr;33(4):233-43.
4. Asanoma K, Kubota K, **Chakraborty D**, Renaud SJ, Wake N, Fukushima K, Soares MJ, and Rumi MAK. SATB homeobox proteins regulate trophoblast stem cell renewal and differentiation. *J Biol Chem*. 2012 Jan 13;287(3):2257-68.
5. **Chakraborty D**, Rumi MA, Konno T, and Soares MJ. Natural killer cells direct hemochorial placentation by regulating hypoxia-inducible factor dependent trophoblast lineage decisions. *Proc Natl Acad Sci U S A*. 2011 Sep 27;108(39):16295-300.

Abstracts Presented:

1. **Chakraborty D**, Rumi MA, Krieg AJ, and Soares MJ. Role of hypoxia signaling in trophoblast cell lineage commitment. FASEB Science Research Conference on Transcriptional Regulation During Cell Growth, Differentiation, and Development, Snowmass, Colorado July 15-20, 2012
2. Rumi MA, **Chakraborty D**, Asanoma K, Kubota K, Bu P, PhD, Renaud SJ, and Soares MJ. Transcriptional hierarchy of SATB homeobox proteins in trophoblast stem cells. Fetal Programming and Environmental Exposures: Implications for Prenatal Care and Pre-Term Birth. The New York Academy of Sciences, NY June 11-12, 2012.
3. **Chakraborty D**, Rumi MAK, Krieg AJ, and Soares MJ. Role of hypoxia signaling in trophoblast cell lineage commitment. Poster presented in 8th Annual Gilbert S. Greenwald Symposium on Reproduction, Kansas City Kansas, Missouri, 2011
4. Asanoma K, Kubota K, **Chakraborty D**, Renaud SJ, Soares MJ, and Rumi MA. SATB homeobox proteins regulate trophoblast stem cell renewal and differentiation. Poster presented in 8th Annual Gilbert S. Greenwald Symposium on Reproduction, Kansas City Kansas, Missouri, 2011.
5. Rumi MA, Kent LN, Lee DS, **Chakraborty D**, Konno T and Soares MJ. Rat placental lactogen II promoter directs trophoblast giant cell specific expression. Gordon Research Conference on Reproductive Tract Biology, Andover, New Hampshire. Aug 15-20, 2010
6. **Chakraborty D**, Konno T, Soares MJ. Uterine natural killer cells: Homing and their effects on rat placentation. Poster presented in fourth Annual Gilbert S. Greenwald Symposium on Reproduction, Kansas City, Missouri, October 9-11, 2008.
7. **Chakraborty D**, Konno T, and Soares MJ. Uterine natural killer cells: Homing and their effects on rat placentation. Poster presented in Gordon Research Conference on Reproductive Tract Biology, Proctor Academy, Andover, New Hampshire, August 3-8, 2008.
8. **Chakraborty D**, Konno T, and Soares MJ. Role of uterine natural killer cells in rat placentation. Oral presentation in Student Research Forum (SRF), University of Kansas Medical center, Kansas City, Kansas, April 11-12, 2008.

9. **Chakraborty D**, Konno T, and Soares MJ. Uterine natural killer cells: Their effects on rat placentation. Poster presented in fourth Annual Gilbert S. Greenwald Symposium on Reproduction, Kansas City, Missouri, October 5-6, 2007.
10. **Chakraborty D**, Varghese AC, Mukhopakhaya D, Bhattacharya SM, Bhattacharyya AK, and Agarwal A. Motility characteristics and DNA integrity of spermatozoa processed with different concentrations of reduced glutathione (GSH). Poster presented in 62nd annual meeting of ASRM, Louisiana, New Orleans, October 2006.
11. **Chakraborty D**, Varghese AC, and Bhattacharyya AK. Study on pronuclear morphology and cleavage kinetics as scoring criteria for selection of best embryo for transfer. Poster presented in International Conference on Male Reproduction and Infertility, Indian Institute of Science, Bangalore, India, September 16-18, 2005.
